Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. A Course of Lectures
ON
DISEASES OF THE TONGUE,
DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,

By Prof. JONATHAN HUTCHINSON, F.R.C.S., F.R.S.;

President of the Pathological Society of London; Professor of Pathology in the Royal College of Surgeons; Senior Surgeon to the London Hospital.

Lecture I.

It has been said of a well-known poet that he used the works of some of his predecessors as if they were simply quarries to furnish stone for his own building, and no special censure was intended by the remark. It is indeed impossible that any author in the present day should avoid using the materials gathered ready to his hand by others; nor is it, indeed, in the least desirable that he should attempt to do so, his primary duty being simply to build well.

In the present course of lectures I by no means intend to treat systematically of diseases of the tongue, but rather to select certain special topics to which my own attention has been attracted, and upon which I have collected facts which may in some sense, I trust, be accounted original. I am very conscious, however, that even in respect of these I have been indebted on all hands to the labours of those who have gone over somewhat the same ground before me. I shall endeavour, whenever I am conscious of special obligation, to make a special acknowledgment of it; but in order that I may avoid references of this kind which would become tediously frequent, I wish at the outset to say that, whilst preparing these lectures, I have read with special interest and profit the admirable article on the Tongue, by the late Dr. Hyde Salter, in Todd and Bowman's Cyclopædia; the well-known monograph of Mr. Fairlie Clarke, and several essays of Professor Fournier, of Paris. Papers of real merit on special subjects connected with the pathology of the tongue are too numerous for me to mention here, and from not a few of them I shall have to make quotation. In connection with this subject I must not neglect to offer my best thanks to the staff of Guy's Hospital, who, in the most liberal manner, have placed at my disposal an unrivalled collection of original drawings. It will probably save trouble in the end—indeed, it seems almost unavoidable—that I should devote the greater part of this lecture to preliminary statements, and to the attempt to define and limit some of the terms in use. In the first place, a few words must be said as to the topography of the tongue. It is convenient for purposes of clinical description to divide its dorsum into two lateral and a central portion, the latter being again cut into two by a furrow down the centre, more or less well marked in most tongues. The tip of the tongue, for our purposes, includes the whole of the end, with a little of the adjacent surface both above and below; and to prevent confusion, the term "side" must be held to be equivalent with the edge, passing, of course, a little on to the surface above and beneath. The circumvallate papillæ form a natural boundary to that part of the tongue which is visible without artificial aid, and to that part upon which papillæ abound. In front of them, and extending forwards for about an inch in the middle of the organ, is a very important region, which may be termed the mid-dorsal tract, occupying as it does the middle of the tongue, both from before backwards, and from side to side. On this region several peculiar symptoms are frequently displayed: it is the part which is most exempt from contact with the palate and teeth, and on it the development of the filiform papillæ is unusually abundant.

I do not purpose before this audience to give any, even the briefest, sketch of the anatomy of the tongue. The papillæ with which it is clothed take such an important share in the production of most of the symptoms which we are about to examine that it will, I think, be convenient to remind ourselves of a few facts as to their condition in health, and especially as to their variations, irrespective of disease.

We will put aside the papillæ circumvallatæ, which, arranged in a sort of V, make a posterior limit to the portion of the tongue which is easily visible. It would seem that they are very little liable to be affected by disease, and I shall have little to say about them further than they vary much in size in different persons, and that the experience recorded by Morgagni is often repeated in the present day, and that patients, or even surgeons, discovering these structures for the first time, and of unusual size, mistake them for new growths. Concerning the others—filiform and fungiform—I must speak at more length, for they are concerned in almost every symptom of disease that the tongue displays. The fungiform papillæ are usually met with, shaped somewhat like a bee-hive top, or, as their name implies, like a mushroom. These forms are, however, by no means constant, and it is not uncommon to see them of a club shape, or enlarged in the middle and tapering at both ends. Whatever their shape, they differ from the filiform in being almost smooth on their surface, and, having but a thin epithelial investment, the blood which they contain is easily seen through this covering, and they are usually easily recognised as florid points. They are more easy of recognition, and possibly more abundant in young persons than in the aged; they are said to occur chiefly near the tip of the tongue, being more sparingly sprinkled over its middle. Sometimes they are arranged in lines. They vary, however, very much in different individuals both in size, in number, in form, and in location; and it is, I am sure, by no means infrequent to find them in considerable abundance on the middle of the organ, and even far back on its surface. Of their abundance in this position, our museum affords excellent examples. Although usually the difference between a fungiform and a filiform papillæ can be easily made out, yet they appear to slide by almost insensible gradations into each other, and in many states, both of health and disease, it is not a little difficult to tell which is which. The fungiform never, in a strict sense, take fur, and thus in furred tongues they are for the most part readily recognised; under other conditions, however, when the filiform have lost their hairs and become flattened, it is difficult to be sure that they do not belong to the smaller types of the fungiform.

The filiform papillæ cover in a sort of pile or nap the whole surface of the organ. They are compound structures bearing on their free extremities tufts of hair like elongations, which often exceed by two or three times, the length of the papillæ itself. These processes are clothed with squamous epithelium arranged in an imbricated fashion, and often not firmly attached. They almost always end in points; they resemble hairs not only in appearance, but in structure, and sometimes contain a medulla, and differ in no respect excepting their softness from minute hairs. The tendency to their production seems to vary as much in different individuals as does the growth of hair in the skin. On many healthy tongues the filiform papillæ are short and but little tufted, whilst on others they present a very considerable length so as to admit of their being turned aside by the fingers, like the pile on a piece of velvet. They appear to grow best whenever they are let alone and exempted from friction and pressure. Thus the finest specimens that I have ever seen, occurs in the preparation which I produce. It is the stump of a tongue from a man who died of cancer of the organ under the care of Mr. Liston. Only the posterior third of the organ remains and it is covered in the middle by filiform papillæ, closely set, very slender, and at least a quarter of an inch in length. The organ had been long fixed in the mouth and no doubt this particular part of it had been entirely exempt from pressure.

A remarkable peculiarity, and one which did not escape the notice of Dr. Hyde Salter, of the filiform papillæ is the rapidity with which they can lose and regain their epithelial investments. These hair-like appendages are at all times easily scraped or rubbed off, in many processes of disease, however, something more than their detachment occurs, and patches so smooth are produced that we are forced to believe that all the papillæ over the area involved have undergone a temporary atrophy. It is to this condition that the term "bald patch" is applicable, before saying more, however, on this subject at present, I must describe the condition known as fur. In order that fur should be present two conditions are necessary. First that the tongue, or, at any rate, the furred part of it, should be well clothed, with long, well branched filiform papillæ; and secondly, that these papillæ should have been left at rest and allowed to collect upon their tips the well-known white and somewhat slimy substance which, in a more restricted use of the word, constitutes fur.

Until recently, it was generally taught and believed that this slime consisted of sodden epithelial scales.

The accurate microscopic investigations of Mr. Butlin have taught us that this explanation is only in part true, and that the chief constituent is of fungus origin. It consists in fact of a glœa in which micrococci and bacilli are the chief elements. Not only as Mr. Butlin has shown is this the case with the fur in states of disease, for these fungoid elements are present wherever, even in states of the most robust health, a white fur is visible on the tongue. They have therefore no pathological signification whatever, and having recognised their existence as constituting fur, or at any rate its living part, we must examine the meaning of the fur as a symptom under its different conditions, with but little further reference to them. It is of importance, however, that we should remember when reading the observations of those who have thought that they had discovered fungus growth on the surface of the tongue as a cause of disease, that certain forms of plant life are almost invariably present, and may in some instances have led to error. In reference to the so-called "ring-worm of the tongue," however, the difference in size between the spores of the trichophyton and the micrococcus shown us by Mr. Butlin is so great that confusion can scarcely have occurred.

As I have just hinted, the conditions which favour the development of fur on the tongue, are briefly those of rest. If we can fully realise this fact, it will help us to the explanation in a very simple manner of most of the morbid conditions of the tongue met with in acute diseases. When the tongue is quiet, the papillæ grow freely, their hairs accumulate epithelium, and on the epithelium colonies of micrococci flourish. Large allowance must be made for individual peculiarity, for it is only in those in whom the filiform papillæ are abundant and large that any development of fur can possibly take place. It is well known that most persons have more or less coated tongues before breakfast, and that the taking of a meal rubs off the fur and cleans the tongue. It is also well known that when the tongue cleans it usually does so from its end and sides; leaving the middle of the dorsum and especially the posterior part still covered. The explanation of this is easy, for the parts which clean first are precisely those which are most rubbed against the teeth and hard palate.

It is very common to see tongues which do not clean in the manner just described, but in which one longitudinal half of the tongue is clean whilst the rest is furred. In these cases the line is never abrupt in the middle, but it is usually to be noticed that considerably more than half is clean and less than half as it may be a mere streak on one side remains furred. The explanation of this condition is I believe always to be found in the fact that the patients in whom it is observed eat chiefly or only on one side of the mouth.

It does not matter in the least what the cause of the one sided mastication may be, whether there is a tenderness or the absence of teeth, the result is just the same. If a patient eats on one side only of his mouth he rubs that side of his tongue much cleaner than the other. I am of course aware that one of my distinguished predecessors in this chair, the late Mr. Hilton, an observer and a reasoner from whom I would differ with great diffidence and reluctance, propounded another theory, and that his suggestion has been widely accepted.

Mr. Hilton's observations of the facts were exactly the same as my own, at any rate thus far, that he noticed that those who had aching or tender teeth got the tongue furred on the side of the bad tooth. His explanation was that the fur was produced in a reflex manner through the influence of the fifth nerve, and was an instance of disturbance of function and nutrition by nerves.

Apart from the consideration that it is desirable to avoid calling to our aid nervous disturbances, concerning which we can prove nothing, when they are not required; I must contend that the simple mechanical explanation which I have given covers the whole ground and accounts for a large number of cases which the other would fail to explain. It is certainly not the fact that painful teeth are present in all cases of unilateral furring of the tongue. In many, I think in the majority, the condition is rather the absence of teeth.

The condition of accumulation of white or dirty brown fur in the back part of the mid dorsal region is exceedingly common. It is to be explained in the same manner that we have suggested in the case of unusual growth of the filiform papillæ in this region, being, indeed, to some extent, the same thing. This is the part of the tongue the best protected from pressure and friction, and upon which both papillary and fungoid growth takes place, therefore, most easily. When fur collects in patches in local regions elsewhere than in the middle, some local peculiarity in the mouth is to be suspected. There may be a sore on the palate, making it painful to apply the tongue to that part, or there may be an aching tooth, or a gap in the row of teeth, or a sharply broken stump. Any of these conditions may favour the occurrence of patches of fur, but such patches are seldom well defined or very conspicuous.

Absence of fur—a simply clean tongue—is indicative, usually, of a good appetite and free mastication in all parts of the mouth. It generally implies, in addition, that the development of the filiform papillæ is only moderate. On the other hand, an habitually foul tongue without dyspepsia or ill-health, usually indicated an excessive growth of these papillæ and their appended processes.

The term "bald patch" is applicable to the condition in which the papillæ have disappeared from a local area, as that of "bald tongue" is to be used when the whole, or almost the whole surface is denuded. The baldness of the patch may be either partial or complete. It may be that even with a lens no trace of any form of papilla is to be distinguished. The bald area may be simply denuded of its papilla, or it may be, at the same time, somewhat swollen. When there is a distinct, abruptly margined elevation having a flat table-like top, the condition is that to which the name condyloma is given. It is seldom or never seen, excepting in connection with specific disease, and at an early stage of it. Elevated ridges, however, or roundish patches, ill-defined and always higher in the middle than at the edges, that is, not table-topped, bald, smooth, and even glossy on their surface are often seen, both in the later stages of syphilis and also in leprosy.

They differ from the condyloma anatomically, in that the swelling is more deeply situated, and does not involve the papillæ themselves, which are, indeed, wholly destroyed. In the true condyloma, although the hair of the papillæ are lost, and consequently all fur is absent, the papillæ themselves are in a state of hypertrophy, but matted together by the swelling of the connected tissue.

Bald patches on the tongue have been termed psoriasis, but—as I shall have to remark in a future lecture—they are scarcely ever seen in association with psoriasis of the skin, excepting, indeed, when the eruption is syphilitic.

When the denudation of the papillæ is complete, and the deeper layers of the mucous membrane congested the condition is assumed to which the term raw tongue is applicable.

There is a form of local baldness of the tongue met with chiefly, but not solely, in children to which the term ringworm of the tongue has been given. I will ask permission to use this term provisionally as denoting all crescentic orbicular or circinnate patches of denudation which look like ringworm. At the proper time I shall have a good deal to say on this subject, but for the present, and perhaps for some time to come, the term in question must be used without either affirming or denying that the malady in question is really due to the ringworm fungus. These patches are usually seen on the sides, or near the tip of the tongue; they are remarkable for their very definite outline and rounded borders, destruction of the papillæ and a bald red surface is their constant feature.

It is now some years since I proposed that, instead of the widely inclusive clinical name Ichthyosis, which implies much more than we here mean, we should use for all white patches on the tongue the simply descriptive epithet of leucoma.

In France the term leucoplasia, or leucophakis, has come into use, and I believe it is generally felt to be important to discard that of Ichthyosis. It is to be understood that the white patches of which we now speak have nothing to do with fur. They are produced by a process of chronic inflammation, or of secondary sclerosis involving either the denuded papillæ or the deeper layers of the mucous membrane.

The most common and the most conspicuous, those which indeed have hitherto almost solely claimed attention, are due to sclerosis of the deeper layers, and may in advanced cases become very dense and thick. They may occur in patches or be diffuse over the whole surface. The anterior part of the dorsum is their favourite locality, but they may extend to the sides and even to the under surface. Now and then they are present in the palate also, and very often in the cheeks. Their limits of variation as to thickness are very wide; they may be as thin as the white tracts left by a snail (the filmy leucoma), or as thick as kid leather. For the most part smooth on their surfaces, they may occasionally be rough or even spinous (leucoma aspera). Being formed in the mucous membrane, they cannot be detached without causing bleeding. Their presence is always indicative of previous atrophy of the papillæ, but this may not have been absolute.

For the most part, when once found, they are permanent, and tend to increase in thickness and in extent.

There is another kind of white patch, which deserves the name of leucoma, but which we must carefully discriminate from that just described. It is not permanent, and does not imply any papillary atrophy. The papillæ are indeed themselves involved in the change. I refer to the patches which are now well known to occur in a large number of cases of lichen planus, and which were, I believe, first distinctly associated with that disease by myself in 187 , although a single example of them had been previously recorded by my friend, the late Dr. Sparkes. These patches, as shown in the diagrams, are usually seen on the lateral regions of the dorsum. They are punctate at first, but by confluence, as is the case in the skin eruption of this disease, they often constitute in the end large irregular patches.

They are never quite smooth, and never absolutely white. Concurrently with them, there are almost invariably present small punctate leucomata in the pouches of the cheeks.

Sometimes well-marked patches of the kind described are met with on the tongue and cheeks without any associated eruption on the skin.

(*To be continued.*)

◆

The vacancy on the Examiners' Board at the Royal College of Surgeons of England, will be filled up at the quarterly meeting of the Council on Thursday, July 12. Candidates, who must be Fellows of the College, should send in their names immediately.

Lectures
ON
THE RELATION OF THE TUBERCLE BACILLUS TO PHTHISIS. (a)

By C. THEODORE WILLIAMS, M.A. Oxon., M.D., F.R.C.P. Lond.,
Physician to the Hospital for Consumption, Brompton.

Lecture II.—Its Influence on the Clinical History and Treatment.

The relation of the bacillus to the various states of the lung, as evidenced by physical diagnosis, was considered by the lecturer, and it was shown that even in the early stage of consolidation bacilli might be detected in the sputum. In the case of a young woman, aged 17, with a history of slight symptoms of 3 months' standing, in whom only tubular sound without dulness could be detected at the right apex, with occasional fine crepitation and cough, a few bacilli were found, though the cough was almost *nil* and the expectoration extremely scanty. The extension of the disease is generally accompanied by either an increase in number, or, if the bacillus have previously disappeared from the sputum, by their reappearance. In one well-marked example of an active first-stage case, the numbers of the bacilli corresponded exactly to the activity of the tuberculisation, and when the disease became quiescent, they disappeared from the sputum. This instance would illustrate the doctrine that the bacilli may enter the lungs and not the body, for though the soil would seem to have been well prepared by family predisposition, the general health was excellent, and there was fair hope of the disease remaining localized. Other cases were cited to prove this, and in one, a case of advancing tuberculisation, the interesting feature was that the spread of the crepitation downwards was preceded by—1st, a division of the bacilli, and 2ndly, by their being found in greater abundance ten days later, and afterwards they were still found to vary considerably in length, as if there was a prospect of further multiplication and a consequent spread of disease. In another case the extension of the mischief was indicated by the collection of the bacilli into small groups, and in this case there was in their appearance much diversity: some were simple rods, without markings, others had the beading well marked, while in a third class the form was more or less sinuous.

The lecturer was of opinion that the number of the bacilli present indicated the amount of irritation and cell proliferation taking place in the alveoli. Moreover, when a small and quiescent cavity exists in one lung, and the physical signs indicate an extension of tuberculisation in the opposite lung, without any defined spot of coarse crepitation or gurgle, to indicate that excavation is going on, it is justifiable to connect any increase in the number of bacilli with the fresh tuberculisation, and not with the discharge from the quiescent cavity. The relation of the bacilli to the process of *excavation* is very intimate, and the numbers increase greatly while this is proceeding; even when no extension of a cavity is taking place, they are detected from time to time as long as there is any discharge. Two good illustrative cases were given in which the bacilli fluctuated in number according to the extent of the excavation process, nearly disappearing when the cavity had formed and become quiescent. In the latter case, that of a middle-aged man with a strong family history of asthma, and who had suffered more from dyspnœa than cough, the physical signs of catarrh almost masked those of phthisis, and had it not been for the abundant expectoration, the formation of a cavity might not have been suspected. The appearance of numerous bacilli in the sputum placed this beyond a doubt, and when the catarrhal sounds passed away, cavernous breathing was heard without difficulty at one apex.

In cases of quiescent cavity we find bacilli present in numbers corresponding to the amount of expectoration, which as a rule is small. When the cavity contracts this may be reduced still more, and in many instances the bacilli cease to appear in the sputum, not because they no longer exist in the lungs, but rather because the communication between the cavity and the bronchus being blocked by the increasing lung contraction, they cannot escape with the now purely bronchial sputum. A good instance of this state of things was shown. Many cases of contracting cavities, with no great dislocation of adjoining organs, and where cavernous sounds are barely audible, yet show bacilli in the sputum, because the bronchus leading to the cavity remains patent; but if these are few in number and there is strong evidence of fibrosis, their presence need not much modify the prognosis; but on the other hand, where a cavity opens into the pleura and pneumothorax results, the numbers of bacilli increase considerably.

It was shown from cases that the presence of tubercle bacilli in the lung secretions does not affect the gain or loss of flesh in the patient; but as to pyrexia, there is less certainty, though it is clear that they may be present in non-pyrexial cases. When fever accompanies tuberculisation and excavation, they increase largely, whether from local processes or from general irritation. In the case of a young girl with a cavity at one apex and some tuberculisation at the other, the temperature ranged from 100° F. to 103·6° F. for fourteen days; but it was not till the fourth specimen of sputum had been tested that any bacilli at all were found; and in another young girl with double cavities and a high temperature course, bacilli were found very scantily. A third case, also with two cavities, had pyrexia from 100° F. to 103·6° F. for sixteen days, with very few bacilli in the sputum: while in some cases, where they are particularly abundant, there is no pyrexia, and the explanation seems to be—1st, in the fact that tuberculisation, and especially excavation, may take place without pyrexia; 2ndly, that examination of sputum only teaches what is going on in the lungs, which in cases of acute pulmonary disease certainly means a good deal, but when the blood is poisoned and the system generally becomes infected, we must not expect the sputum alone to give the explanation, which should also be sought for in other secretions. At present the testings of the blood have failed to do so, but the lecturer had no doubt this would not always be so.

The *infection* of phthisis is rare, though the opportunities for it are common, the air of the streets being probably impregnated with the exhalations and the dried sputum of the consumptive.

Dr. Williams adduced the statistics of the Brompton Hospital resident and non-resident staff for the last thirty-seven years to show the extreme rarity of phthisical infection. Out of several hundreds of resident medical officers, clinical assistants, matrons, nurses, and servants, there were only two instances of phthisis supervening during their period of residence.

During periods of defective ventilation, erysipelas and sore-throat had appeared among the in-patients; but even under these conditions, when the bacilli would be likely to accumulate, there had never been any instances of infection among the non-consumptive patients. When infection did take place, it was either (1) through inhalation of the breath of the consumptive, as might occur in people sleeping together in a badly-ventilated room, or (2) by coition, as in the case of husband and wife, so well demonstrated by Dr. Hermann Weber, or (3) by living on the milk or meat of diseased animals, of which several cases had been described on the Continent. The proper means to avoid such infection were—1. Good ventilation; 2. The separation of the consumptives at night; 3. The removal, and if possible, destruction of the sputum; 4. The prohibition of the marriages of phthisical and healthy persons; 5. Careful inspection of food. The lecturer was of opinion that if these precautions were taken the infection of phthisis would be quite unknown.

(a) Abstract of Lecture II., delivered May 9th, 1883.

The treatment of phthisis on antiseptic principles most people understood to mean wearing a respirator containing carbolic acid or creasote, and Dr. Williams had found this practice, though soothing to the cough, absolutely useless in combating the disease. It was doubtful if many of the drugs used in this way penetrated to the lungs. Respirators also impeded the action of the jaws, and interfered with free respiration. A second method was by impregnating steam with various kinds of antiseptics, and this was done most effectually in the steam-spray rooms of the new hospital. A third form was by diffusing the air of the patient's chamber with various medicated vapours, such as iodine and chlorine, which was also done in certain wards, thus imitating some of the varieties of climate. Lastly, various forms of antiseptic medicine should be given in the form of arsenic, quinine, and cod-liver oil, which had long been shown to be of marked efficacy in the treatment of phthisis, and must be combined with the best food and with pure air, all of which acted by enabling the patient to withstand the attacks of the tubercular virus, even if they were not actual antidotes to the Bacillus tuberculosus.

◆

ON THE HYGIENE OF ARMIES IN THE FIELD. *(a)*

By ROBERT RAWLINSON, C.B.,

Chief Engineering Inspector to the Local Government Board.

THIS subject is so vast, special, and complicated, that I can only promise to touch the fringe of it, and this in a roundabout way. I will not presume to lay down hard and fast rules by which armies in the field shall be regulated in sanitary matters in the future, but rather describe, in narrative form, some of my own experience, gained during the time I acted as the engineer member of a Sanitary Commission sent out to the army in the Crimea in the spring of 1855.

[Mr. Rawlinson proceeded to read the instructions issued to this committee. It was directed to investigate the condition of every hospital, infirmary, or receptacle for the sick, both as to interior ventilation and cleanliness and exterior surroundings. At the same time, the fullest powers were given to the Commission to obtain labour and other assistance for the carrying out of their recommendations. Mr. Rawlinson then resumed as follows.]

If General Orders could in all cases have been made applicable, and could have been obeyed, outside comment might cease, and the aid of a specially appointed Sanitary Commission during the Crimean war might not have been needed. It may, however, from experience, be assumed that there never will be General Orders framed sufficient to cover all contingencies; and we may also assume that there will be neglect now and then from various causes. Some of the links in the chain of regulations will break, and confusion will follow. The General Orders for the army under the command of the Duke of Wellington in the Peninsula, in the Low Countries, and in France, 1809 to 1815, cannot probably be improved upon. Lord Raglan was secretary to the Duke, and he must consequently have been acquainted with the Duke's General Orders; and yet we see the utter confusion into which affairs drifted in the Crimea. The siege of Sebastopol became, however, exceptional.

To whom the failure in the Crimea was due it is impossible now to say. It was not, however, to any individual, but rather to the absence of an independent sanitary department with the army, and to the want of one home department to direct and control, having also power to order all stores, and to inspect their shipment, and to see that the several stores were so arranged in the transports that they should be available in the order of their necessity, and not to have surgical appliances and medicines placed beneath a massive bulk of ammunition. Blunders of this class do not appear to have been avoided, even in the recent Egyptian campaign. The Royal Commission, which, under the presidency of Lord Herbert of Lea, inquired into the sanitary state of the army after the Crimean war, resulted in Lord Herbert's regulations. One of these regulations provided that a sanitary officer should be attached to the quartermaster-general's staff. To this officer was to be committed the duty of examining into the sanitary condition of buildings selected for occupation by troops, and into the sanitary condition of towns or villages about to be occupied; he was also to make recommendations for organising a proper sanitary police, to preserve cleanliness, and for the removal of nuisances. But it will be seen that practical lessons, however well taught, and also that subsequent official inquiries, however ably conducted, have led up to very little that has proved to be really useful when the country again enters upon war. The army medical arrangements had drifted back into the old groove, the old form of blunders and the old stories are repeated—namely, that the existing regulations are supposed to be, if not perfection, all that is requisite. In Government departments I am sorry to say that there is not, on all occasions, due respect shown to the feelings of permanent officials; and in our case we were not put into communication with the heads of the permanent medical department before leaving London, which, no doubt, gave offence, but for which the members of the Commission were in no sort of way answerable.

[Mr. Rawlinson proceeded to state that when the Sanitary Commission arrived at the seat of their labours, they found the buildings used as hospitals in an unsanitary condition; the sewers of the great hospital were foul, and required frequent and thorough flushing, and their lower ends were covered to prevent the wind blowing up them into the building; the carcases of a certain number of animals which lay in the neighbourhood of the hospital were removed and buried, and many handcart loads of filth were also removed. The work of scavenging was carried on systematically until the hospital ceased to be needed, owing to the departure of the troops.]

Mr. Rawlinson then continued as follows: The Blue Book Report (1883) on the organisation of the Army Hospital Corps in Egypt reveals many blunders of a type as old as the service, such as confusion in transmitting materials for use; and something worse than confusion in contract supplies, both of materials and of provisions. Can there be no better service in future? War is a blundering, extravagant, and destructive business under any aspect; and the best framed regulations come to be disregarded, and even where adhered to, they may at times be the worst possible extravagance. The Egyptian Report, 1883, most fully sets forth the confusion into which the regulations fell, and the suffering which resulted. Detachments of the army had, however, to be removed suddenly, and the *impedimenta* necessary for use could not follow as rapidly. The provision was made for contingencies which never happened, and, most fortunately for the men, the war came to an abrupt and unexpected termination.

Men in war are loaded like beasts of burthen. They have to march under their *impedimenta;* the whole body may be bathed in perspiration; feeding must be irregular, and water may be absent or may be polluted, and in one night's bivouac the body may be chilled, so that fever to a large proportion of the men must be the result; and that there must necessarily be great loss of human life in actual war will be self-evident to any one who knows the least possible about the subject. No forethought can fully guard against excessive changes in weather. The fighting portion of a soldier's life is of short duration. It is not in battle that armies are destroyed, but on the field, in camp, and in hospital.

Any buildings to be used by sick, or by broken-down and wounded men may, as taught by Sir John Pringle, have the windows removed to prevent injury by polluted air, and any improved apparatus provided for water-supply be brought into use. Food in a concentrated and portable form may also be served out, and the horrible salt junk and ration-pork be in future dispensed with. A spirit-ration is liable to be most injurious in several ways, and should not be used except as a medicine.

For water-supply, light carts of steel, similar in form to watering-carts in towns, may be of great utility, as one horse or one mule would easily draw to a distance of one or two miles from 100 to 200 gallons of water, to be served out to the men in the positions occupied. Portable water-filters can also be easily arranged, to be similar in form to the light steel water-carts; so that water for hospital purposes may be filtered even in its transmission.

(a) An address delivered at the Parkes Museum of Hygiene, June 21.

Where an army for a time becomes stationary, a sanitary corps will find ample work to do in improving roads, in surface-draining, in scavengering, and in ventilating any permanent buildings used as hospitals; and if the service will permit of a use of working parties, enormous benefits may be secured to entire force in the field. A skilled sanitary officer will be a man of many expedients springing from close and intelligent observations; and, in his works, he will strive to save labour. Every country has its character impressed on its surface contours, and these the geologist and engineer will read at a glance. Wide and flat areas will indicate, as a rule, a soft subsoil; a steep gradient will indicate a subsoil of some hard material, such as gravel; rock will generally show above surface; where there are mountains, there will usually be, at the base, mounds of material, particles weathered from the rock and admirably suited for road-forming, as it may be excavated and sorted so as to save the labour of quarrying and breaking for road-making. In future wars it is admitted that picks and spades may require to be used as much, if not even more, than rifles. All officers will, therefore, have to learn something of engineering. If soldiers can use pick and spade to provide earthwork shelter from rifle bullets, they may also use these implements for sanitary purposes. A working army will be more contented if they find that their labour tends to their safety and comfort. Idleness is an incentive to vice, and leads to insubordination. A modern army will be a very different body of men to those forming the Peninsular army under Wellington, and must be treated very differently. Flogging is for ever done with, and it is most disgraceful to have any attempt at its renewal.

The general orders of the Duke of Wellington are considered good examples; but the Duke, in the Peninsula, ever did something more than unceasingly refer to even his own general orders. His personal observation was incessant, his perceptions rapid; and consequently his instructions, outside any order book, were practical, being suited to the conditions and requirements of place and time. The suggestions of the great Duke point to something to be done by the commanders of regiments outside of cut and dried formal regulations.

I think it may be gathered from my remarks, that I do not set myself up as a practical teacher of army hygiene in the field. The purport of this paper is rather to show that, to preserve an army in health, either in barracks or in the field, will, as in the past so in the future, require active intervention on the part of the commander-in-chief, of the generals, and of the colonels and officers, outside any printed regulations, however full and ample. As the Duke of Wellington explained on one occasion to the House of Lords, that martial law was no law other than the will of the commander-in-chief; so, in future, the commander-in-chief, during a state of war, must have the power to relax any published general order or regulation if necessary, to make better provisions for the army. A sanitary staff, as provided for by the late Lord Herbert, distinct and separate from both Commissariat and Army Medical Departments, should be with and part of the army, under the direct control of the commander-in-chief, who shall have power to order and expend in this service as he may think necessary, that is, that any amount of extraneous labour may be provided and paid for which he deems necessary, and the country in which he is can supply.

The army in the Crimea was saved in a great measure by voluntary efforts from home, by relations, and the general public shipping out warm clothing, by Florence Nightingale and her lady nursing, by distribution of food suited to sick men in hospital, and by extra voluntary furnishing of medical comforts, and also by the labours of the Army Sanitary Commission. The expenditures by all these parties were, however, mere fractions in the gross cost of the war; if these entire extras had been provided for, it would only have amounted to about half a week's expenditure of the cost of the war.

In touching on this question of army hygiene, even at this day, I know that I am venturing on disputed ground. But that enormous improvement took place in the British army in the Crimea from some cause or causes, after the advent of the Sanitary Commission cannot be disputed; but officially the credit has never been accorded to that Commission. The one great fact was, however, made unmistakable—namely, that from the spring of 1855 the health and condition of the British army began to improve, until, by the autumn of that year, the entire force in the field was in a state of health, and was under a less rate of mortality than when in barracks at home, and this continued until the close of the war. The French, the Sardinians, and the Russian soldiers, however, knew of no such abatement of camp and hospital sickness, the destruction of life having gone on up to the close of the war. Full details may be found in the Army Returns of the several nations, and in a pamphlet by Surgeon-General T. Longmore. (a)

Without giving these, I may state that the British army in the first winter had 2,286 deaths from fevers of all kinds; second winter, reduced to 129. Under typhus, from 164 to 16. Amongst the French troops, 90 the first winter, 10,278 the second winter. The French had no sanitary commission, the hospitals remained unscavenged, unventilated, and their hospital drains unimproved, the result being excessive overcrowding, until men and doctors alike perished; the British hospitals being absolutely free from typhus cases. Taking these results into account, Surgeon-General Longmore states: "It is well that the practical lessons in sanitary science afforded by the events of the Crimean War should not be allowed to pass out of mind." In these remarks I cordially agree.

◆

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Two Cases of Perforating Ulcer of the Foot.

By HENRY T. BUTLIN, F.R.C.S.,

Assistant Surgeon and Demonstrator of Practical Surgery.

Case I.—A policeman, æt. 26, was sent to me, in the out-patient room, at the beginning of 1882, on account of perforating ulcers of both feet, which prevented him from walking and therefore performing his duty as a policeman. He had been a member of the Force for seven years, and although he had been in the habit of standing and walking during many hours of every day, and had suffered from corns on both feet, the ulcers had only begun to form about four months previously.

On the 12th of January he was admitted into the hospital. He had then a typical perforating ulcer under the ball of each great toe, and a hard corn under the ball of each little toe. The ulcers were surrounded by the hard and thickened tissue of the corn in the centre of which each had formed. They extended deep down into the subcutaneous tissue, but there was no affection of the bones or joint. The feet were fairly formed and fairly nourished. The patient was very tall, and the circulation was feeble; but there were no symptoms indicative of nerve lesion, either central or peripheral. He was kept in bed, and put on a liberal diet; poultices were applied to the feet.

On January 26th the thickened tissue round the ulcers, now softened by the poultices, was scraped away, and the edges of the ulcers were pared until all the part that was undermined was removed. Lotio plumbi was substituted for the poultices.

The ulcers rapidly healed, and on the 17th February he was able to leave the hospital to return to his duty; but precautions were first taken to prevent recurrence of the disease. An isinglass plaster, spread on felt half an inch in thickness, was applied to the sole of each foot immediately behind and partly around the seat of each of the scars and of the surrounding corn. By this means all pressure in walking was taken off the vulnerable part of the foot. The plasters were ordered to be worn during the day, and to be taken off at night.

Some time afterwards I learnt that he was quite well and at his work.

Case II.—G. R., æt. 48, was admitted into Pitcairn Ward, under the care of Mr. Holden, in March, 1877. He was a lighterman, of very dusky, almost livid, complexion, subject to chronic bronchitis and emphysema. For some time past he had been troubled by the formation of a sore in the foot, which sometimes inflamed so much as to prevent him walking. In the front of the ball of the great toe was a small ulcer, presenting the typical characters of the perforating ulcer, surrounded by superficial inflammation, discharging thin, watery pus, and forming the opening of a sinus which led down to bare bone in the immediate neighbourhood of the metatarso-phalangeal joint. All the front of the foot was dull red or livid, both on the plantar and dorsal aspect. There was no anæsthesia, nor were there any definite signs of nerve lesion After some days' rest in bed and the application of a poultice had allayed the inflammation, Mr. Holden cut down through the sinus to the bone and, finding that the metatarso-phalangeal joint was diseased, excised the affected parts. The patient made a good recovery, and left the hospital with the foot quite healed.

(a) "The Sanitary Contrasts of the British and French Armies during the Crimean War." London: Chas. Griffin and Co. 1883.

Four years afterwards, in 1881, he became an out-patient under me on account of some trivial affection of his hand. He made no complaint with regard to his foot, but, fortunately, I recognised him as the man of whom I had taken notes in Mr. Holden's ward. I therefore examined the foot, and was pleased to find that the scar had remained quite sound since the operation, and that no perforating ulcer had formed in any other part of the foot, although he had been standing and walking without any special care during the previous four years.

Remarks.—I have often thought since the publication, four years ago, of a paper on perforating ulcer of the foot by Mr. Savory and myself in the "Transactions" of the Medical and Chirurgical Society (vol. 62, page 373), that we took rather too gloomy a view of the prognosis of cases of perforating ulcer, and that we devoted scarcely sufficient space to the question of treatment of the disease. I still believe that there are some cases which cannot be permanently cured by any measure short of amputation, and that it may be necessary even to remove the foot and lower part of the leg in order to avert recurrence; but I begin to hope that the cases in which these severe measures are required are very few, and that a large number of patients who suffer from perforating ulcer may be permanently cured by much simpler and less dangerous remedies. I have not yet been at the pains to follow up many of the patients who have been treated in the hospital for this disease during the past few years, but hope to do so at some future time. Meanwhile, the two cases just recorded may be accepted as clear proof that the disease is curable in some instances without amputation, and so completely curable that the patient can return to his ordinary avocation, even when this requires long standing or walking. The second case is especially interesting on account of the joint disease which was present. It was not expected that so permanent a cure would result in so poorly-nourished a foot and so impaired a constitution as this man presented. The after-treatment in the first case, the relief of pressure on the affected part of the foot by means of thick felt plaster, is of great importance, especially where the patient is forced to return as soon as the wound is healed to the duties of an arduous occupation.

ACADEMY OF MEDICINE IN IRELAND.

Medical Section.

A meeting of the Medical Section was held on Friday evening, 18th May, in the Hall of the King and Queen's College of Physicians; Dr. **Wm. Moore**, President, in the Chair.

Dr. **A. N. Montgomery**, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

LIVING SPECIMENS.

Dr. **C. J. Nixon**—Case of aortic aneurism, with patency of aortic valves; anomalous physical signs.

Mr. **Coppinger**—A case of paralysis following gunshot wound of the spinal cord.

SPECIMENS BY CARD.

Dr. **J. Magee Finny**—Nodose condition of the hairs.

Dr. **John B. Story** read a paper on

THREE CASES OF OPHTHALMIC GOITRE.

The cases occurred in three women, two of them being unmarried. The following were the points of interest:—Two of the patients were sisters; and the third exhibited the remarkable, and probably unique, complication of double optic neuritis, which, however, had subsided at the time the patient came under observation. In this patient the goître was more marked on the left side, and the palpitations did not occur until five years after the goître and ophthalmos. In the other two the goître and exophthalmos were more marked on the right side, and the palpitations were the earliest symptoms observed. Mr. Story called attention to the support these three cases gave to the theory propounded by Dr. William FitzGerald in the *Dub. Journal* of March and April, 1883.

The **President** said that, although the disease was almost peculiar to females, he recollected three cases in which it occurred in males, the course being short—not quite eighteen months. On the other hand, he had seen it run on for eight or ten years in females. He instanced a remarkable case in which symptoms of exophthalmic goître occurred temporarily from sudden shock. A young girl opened a letter telling of her brother's death. Her pulse became 140°, with exophthalmos and thyroid enlargement. In forty-eight hours the exophthalmos receded, and her pulse fell to normal. To him the disease appeared to be of neurotic origin.

REMOVAL OF A SMALL POLYPUS FROM THE RIGHT VOCAL CORD OF A LADY.

Dr. **Walter Smith** related a case in which he had successfully removed a small polypus from the right vocal cord of a lady, æt. 30, by Voltolini's sponge abrasion method. About Christmas, 1881, loss of singing-voice came on. This was followed by hoarseness, which persisted for a year. In December, 1882, the patient consulted Dr. Smith, who recognised the existence of a pale red pyramidal tumour attached to the edge and lower surface of the anterior third of right vocal cord. After a short preliminary training, he succeeded in passing a moistened sponge, about the size of a hazel-nut, beyond the growth, and then forcibly withdrawing the sponge through the rima, and bearing towards the right side, was fortunate enough to detach the little tumour, which came up adherent to the sponge, and was preserved. Immediately after the operation voice was restored, the hoarseness had disappeared, and she was able to sing. Six weeks subsequently she reported herself as perfectly clear in voice. The operation is a safe and painless one, and suited to a limited number of cases.

Dr. **Beatty** remarked that the attachment of the tumour to the under part of the vocal cords favoured its removal by Voltolini's method. He had met another case in which, owing to its position anteriorly, this method failed.

Dr. **Henry Kennedy** read a paper on

SOME OF THE FORMS OF DILATATION OF THE COLON.

He began by observing that the affection was frequently overlooked, and in confirmation of this he detailed some cases which were so obscure as to prevent any diagnosis being arrived at, and others in which the diagnosis was wrong. He believed, nevertheless, that a correct diagnosis could be made; but it was necessary that the idea of such a possibility should in the first instance be entertained. The condition of the patients who had this affection was always that of impaired health. With this state, when the patients, who were usually thin, were examined lying on their backs, there was chronic tympany, though not necessarily to a great degree. Pressure on the abdomen did not cause pain. In conjunction with these symptoms, the author stated that the main characteristics of the disease were the fæcal discharges, always dark, pasty, and unformed. He insisted particularly on the persistence of such discharges for weeks, months, and even years, during which periods the patients were constantly subject to attacks of diarrhœa, acute or chronic, and were liable even to perforation of the bowel and rapid death. Having detailed cases, he considered the prognosis should always be guarded. Treatment could much benefit these cases, but he doubted whether a complete cure could be effected.

Dr. **Gunn** asked if electricity had been tried, and quoted a case of atonic condition of the large bowel in which it seemed to have proved of benefit.

Dr. **Finny**, criticising the premisses upon which Dr. Kennedy based his cases, said that, although he had laid stress upon three diagnostics of the state of the colon, he had not adduced any conclusive evidence to show that the condition referred to existed. He, too, bore testimony to the great advantages of galvanism applied by a rectal rheophore in cases of atony of the bowels.

Dr. **WALTER SMITH** said it should be borne in mind that there were great difficulties in applying any anatomical rules to the living subject deduced from the position of parts of the dead body.

Dr. **BENNETT** having also joined in the discussion,

Dr. H. **KENNEDY** replied. He said he did not use electricity in any of his cases, nor had he had any post-mortem examinations. He saw no reason to disassociate the symptoms.

The **PRESIDENT** congratulated the Section on the success of its first session, which had now come to a close.

◆

France.

[FROM OUR SPECIAL CORRESPONDENT.]

EXTIRPATION OF THE UTERUS.—At the last meeting of the Académie de Médecine a member read the notes of a case of total extirpation of the uterus. The patient, a woman of about 35, came to the hospital for advice in reference to a burning sensation felt in the uterine region, with continual hæmorrhage. Examination revealed an epithelioma of the neck of the womb in the second degree or stage. Several styptics having been fruitlessly tried, total ablation of the organ of gestation was decided upon, and the patient consenting, the operation was performed, all due antiseptic precautions being used. From first to last the difficulties which presented themselves in this major operation were of a very insignificant character, and consequently were easily overcome. The result could not have been more satisfactory. At the end of a month the patient left the hospital perfectly well.

CEREBRAL SYPHILIS.—At the Société de Chirurgie, M. Perrin communicated the case of an officer who was affected with cerebral syphilis. This officer, many years ago, received a spent ball in the forehead, which caused a wound of little importance. Some time after he made the campaign of Mexico, when he contracted syphilis. From that time he had a cephalalgia intense and persistent. At the same period appeared a necrosis of the frontal bone and a purulent discharge through the nose. He consulted the celebrated Nélaton, who made a large incision over the sinus and extracted five sequestres. The patient was greatly benefited, and was able to take an active part in the last war. However, the pains in the head continued, but the intellectual faculties were in no way impaired up to four years ago, when he was observed to become irritable and nervous. Symptoms of aphasia presented themselves, and everything indicated a commencement of softening of the brain. It was at this stage that he was examined by M. Perrin, who, learning his antecedents, prescribed iodide of potassium with mercurial frictions. This treatment proved useless, and then M. Perrin decided on practising trepanation in four places. The result was a speedy amelioration with an eventual cure.

◆

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

POLITICS AT THE GERMAN HYGIENIC EXHIBITION.—Speaking of the Presidents of Sections in the Exhibitions, and of the fitness of the appointment of Prof. Guret, of Berlin, as President of the Section of Field Hygiene, the special correspondent of the *Allgemeine Wiener Med. Zeitung* goes on to say that, if the choice in this case was in every way suitable, it has aroused a decidedly disagreeable feeling of surprise in medical circles to observe that the choice of Presidents of Sections has fallen upon some not in the first rank, whilst a Virchow and an August Hirsch have only received appointments as *members* of the Sectional Committees. The reason why Virchow, the first hygienist—a man to whom the city of Berlin is so much indebted, and of whom it is proud—was not placed at the head of the committee (in case he had not the choice of being so, and declined it) can only be found in political causes. "But what grounds have caused the setting aside of Professor Geh. Med. Rath. August Hirsch? August Hirsch is esteemed in professional circles as one of the first epidemiologists, and outside the scientific world he has been only once spoken of. That was when he returned from Russia, three years ago, from a journey of investigation into the plague at that time rife in that country—a journey undertaken at the instance of the Imperial Government. He had sent in his report to the proper authorities, the Imperial Health Office, and awaited their decision. As this was too long in coming, and as the Health Office made no sign of noticing his work, he withdrew it, and published it at his own expense. This procedure later on cost Director Struck a very uncomfortable quarter of an hour in the Reichstag, and therefore it may well be that since that time Herr Hirsch has not been a *persona grata* in the higher regions. Such reminiscences cannot be often enough freshened up. They afford in the present case, and in still higher degree for our own *epigonen*, a small but valuable measuring staff, which will aid us in forming a judgment of persons and of the movements of the times."

THE BERLIN POLICLINICAL INSTITUTION.—This institution, founded by Dr. Ludwig Loewe, and carried on successfully by him for the last six months as a school for higher technical instruction to medical men, has just completed its first semestre. From the closing address of the conductor, we learn that during the past half-year monthly classes for instruction in opthalmoscopy, otoscopy, laryngoscopy, endoscopy, and in the use of instruments of precision generally, have been carried on with success assured from the first, and becoming greater with each course. As most medical men receive their licences to practise whilst wofully deficient in practical skill in the use of the many instruments now daily employed in the investigation and treatment of disease, we have no doubt that such an institution, carried on efficiently, will fully justify the hopes of its founder and supporters. It is much more the custom in Germany than in Britain for practitioners to renew their studies at intervals, for which they have ample opportunities in the many short courses of lectures that are delivered at the various schools during the holidays. When our medical men have awakened to a need for holiday lectures, we may then conclude that the time when British Polikliniken shall take root and flourish and become "institutions" is not far distant.

ERGOTININE.—The firm of Gene and Co. have succeeded in procuring the active principle of ergotin, and have named it ergotinine. Experiments have been made with it in the Strasburg laboratory which have proved the preparation to be of extraordinary power as a hæmostatic. It is probable, however, that the price, if not reduced, will interfere to some extent in preventing a widely extended use of the drug. The present price is £10 per gramme, or about 13 shillings per grain. This, however, is much cheaper than the French ergotininum (Tauret), which is said to be £5 per grain.

RESECTION OF THE LUNG.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your French correspondent does not relish correction. This is evident from the unsuppressed sarcasm contained in the last two sentences of his communication, and also from the ungrammatical construction of his second sentence. The warmth of his feelings did not permit him to examine the structure of his sentences even with coolness. 'Tis pity. No one is very angry with him for his mistake; certainly "the Writer of the Summary" is not. The worst that can be alleged against him is that he appears in the present instance to have been unacquainted with the contents of the journal of which he is a valuable and valued correspondent, and that when this was pointed out to him he appears to have preferred the authority of the French publication to which he refers, on a German subject, to that of the *Medical Press and Circular*. But the more this latter allegation is considered the graver it appears—indeed, its gravity is such that only yourself, Sir, as editor, can be in a position to deal with it. To dare for one moment to consider any French journal, or, indeed, any journal, however "well informed," or however "edited," to be more accurate than your own!!

I am, Sir,
The Writer of the Summary.

⁂ We do not think another Franco-German war either necessary or desirable. Our German correspondent simply pointed out the very excusable error into which our French correspondent in common with hundreds of others had fallen in attributing to Koch, of Berlin, the operation of "Resection of Lung" performed by Koch, of Dorpat. Our French correspondent rightly quotes the *Bulletin de Thérapeutique* as his authority, but that journal is mistaken nevertheless.—Ed.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 4, 1883.

CHOLERA IN EGYPT.

That cholera of severe, if not malignant type, has suddenly appeared in Egypt, seems to be beyond all doubt. Already the disease has occurred at Damietta, at Port Said, and at Mansourah, these three places separated from each other by considerable distances. Against the theory of writers who consider that this disease is purely Asiatic in its origin, there is the fact in relation to the present outbreak that the history of direct transmission from India to Egypt is absolutely wanting; the further fact, that in order to support that theory, it becomes necessary to explain how cholera has bounded from Hindostan to Damietta, between which little or no communication exists as compared with other Egyptian ports at which the disease has not appeared. The past history of the disease is replete with examples of its occurrence not only in various parts of India between which and the Gangetic valley—its reputed "home"—no communication could possibly have existed at the time. So also in the case of New Orleans in 1873, Lauffen in 1874; with regard, also, to the outbreaks of the disease in Africa in 1837 and 1870 respectively, there existed no means of explaining whence the epidemic wave came. On the other hand, however, the case of New York in 1848 9 has an important bearing on the present outbreak in Egypt. The disease was introduced into that city in December of the former year, but did not spread; on the contrary, it appears to have remained dormant until brought into activity by the heat and other seasonal conditions of summer. Of course a similar circumstance *may* have happened in regard to Egypt, but like many other points in relation to cholera, so here, facts refuse to chime in with theories and suppositions.

Cholera having occurred at three different places, as already mentioned, does the history of previous outbreaks afford any information as to whether those places are to constitute so many foci whence the pestilence is to spread, or not? In 1856 the disease appeared suddenly, and very severely, in Upper India. Yet there was no general epidemic over the intervening territories. In 1861 the disease in some instances followed branch lines of road, attacking villages similarly situated with different degrees of violence, passing over some to appear in those most distant, and, in certain large stations, attacking sometimes only the natives, sometimes the Europeans, sometimes both those classes indiscriminately. Again, in 1865, the disease having been imported into Alexandria, it there gained force, so to speak, and thence spread with increased virulence throughout the basin of the Mediterranean. Thus, no definite criterion is furnished by such instances whereon to predict what may, or what may not, be the future course of the present outbreak in Egypt. A theory has been evolved that the "diffusive energy" of particular epidemics varies; that when this "energy" is great an epidemic spreads; when weak, an epidemic does not spread. But here, again, a phrase has taken the place of definite explanation. It is a somewhat remarkable circumstance that, of the several epidemics that have extended from India to Europe, the disease has not followed the same route on any two occasions; and so with regard to rate of progress, this has varied from time to time, and on occasions differently at different periods in the same epidemic, the ordinary means of communication by land and sea remaining the same. No doubt, as a rule, when cholera—like any other "zymotic" disease—has manifested itself, insanitary conditions favour the intensity of its prevalence even when they do not directly produce the epidemic—such conditions including not alone dirt, to which the term has of late years come to be in a great measure restricted, but the general state in which the great mass of the poor live. But cholera is by no means limited by and to such conditions. There have been many occasions on which the distribution of the epidemic has borne no relation whatever to conditions of sanitation; where places attacked were in no worse position in this respect than others that were spared; and that this has been the case in India, Europe, and elsewhere.

Much is being written on the subject of quarantine in relation to the present outbreak of cholera in Egypt. There are numerous instances on record in which cholera has passed by land from one district or country to another district or country, notwithstanding the strictest possible employment of sanitary *cordons*. So, also, in regard to sea: although undoubtedly on occasions measures of quarantine have, to all appearance at least, protected islands and ports from the disease, there are also instances, by no means few, where at places visited by cholera the shipping has altogether escaped in the absence of all quarantine measures; and many more in which cholera, although imported into a locality, has not spread. According to ancient Mahomedan hygiene, it was directed that neither ought those who are in an uninfected locality enter one infected, nor those in an infected locality escape therefrom. With the march of civilisation all this is changed, and now, if the newspapers are to be credited, panic-stricken people are fleeing from Egypt by every available means of escape. Are they thus the more likely to avoid the disease? Far from it. On the contrary, their liability to become themselves affected may be added to by the state of terror in which they obviously are, and thus they may become the means of transmitting the disease to places that would otherwise escape.

What, then, ought to be done in order that we in England may be prepared to act with something like efficiency in the event of cholera appearing among us? In the first place, certainly, to avoid "panic." Let us organise a regular system of hospital and medical relief; huts, tents, or buildings to be utilised if necessary; medical men, attendants, and other persons usually required for the purposes of hospitals; means of transport for the infected; means for strict inspection, house to house visitation, distribution of medicine; and let the entire organisation be under a distinct and responsible director. But, we repeat, let there be no panic.

◆

PAPER VOTING IN THE IRISH COLLEGE OF SURGEONS.

At the annual general meeting of the Fellows of the College, on June 2nd, the following motion was adopted without a division:—"That the necessary steps should be taken to have such alterations made in the Charter of the Royal College of Surgeons as shall enable provincial Fellows of this College to vote at the election of President, Vice-President, and Council, by voting papers or other means, as is the case in Trinity College, Dublin, the University of Edinburgh, and other institutions." It was also remitted to the Council to consider the best means of informing the Fellows from time to time of its proceedings.

We greatly regret that no opportunity was afforded for considering this vital change in the constitution of the College before it was submitted for the vote of the Fellows, for we believe that, if the subject could have been debated after due notice, the decision would have been different. Three years ago the Fellows rejected the same proposition by an overwhelming majority, and we know of no circumstances which have since occurred to justify so complete a change of opinion as that which this year's vote is supposed to indicate.

This resolution was urged upon the Fellows on the ground that it is desirable to give the provincialists a larger influence in Collegiate affairs than they are now able to exercise, and if we could think that paper voting would have any such effect we would warmly support the proposition. We have always held the opinion that the College might and should do much more than it has ever done to interest the surgical profession in Ireland in its proceedings, and, with this view, to gather round it the Fellows who are practising surgery in the provinces. It is the duty of the Council, we insist, to make the Fellows aware of its policy and its proceedings, not by a bald and disconnected *rechauffé* of the year's work delivered to them a few days before the annual meeting, but by a quarterly *précis* of everything done in the Council, and a fair open disclosure of the votes of Councillors on all important questions.

We, therefore, assert the rights of the provincial Fellows as loudly as any advocate of paper voting can do, but it is, nevertheless, our belief that no step could be taken which would be more likely to extinguish the provincial influence in the College than to encourage the Fellows to absent themselves from the Collegiate meetings, and to content themselves with voting for certain names on a list without any sufficient knowledge as to whether the policy or acts of the Council deserve approval or whether the person for whom they vote deserves to be elected to the executive of the College.

It seems to us that the strength of the College lies in the intimacy of its connection with surgery throughout Ireland, and that such connection can only be a nominal one if the Fellows are induced—as too many of them now are—never to enter its portals, or to take a larger part in its affairs than once a year to register a half-blind vote respecting the *personnel* of the body which is to administer its affairs.

The chief objection which we entertain to paper voting is that it would practically wipe out the independent provincial influence over the acts of the College. It is not proposed, we believe, to extend paper voting to the settlement of questions debated in the College, but to limit it to the election, which is only a part, and not the most important part, of the Fellow's prerogative. He will, if the resolution be carried into effect, be entitled to choose his representatives on the College Council without leaving his home, but, while he gains this privilege (if it be a gain), he will lose the opportunity of voting on any question submitted for the opinion of the College at other times, inasmuch as he would not be present at the meeting of the College to hear or vote.

We apprehend that, in the absence of the independent provincial voter, the teaching party will become masters of the College, of its policy, of its influence, and of its funds. In a small metropolitan constituency like Dublin, a majority of the Fellows have always been, and must necessarily be, connected with teaching, and interested in the emoluments arising therefrom, and the only chance of diluting this influence is the interposition of the provincial voter, who is free from personal interest in these matters. If, therefore, that independent element be eliminated from the meetings of the College by the introduction of paper votes, the teachers will have the College to themselves, and any attempt at educational reform will be useless. There is, indeed, no need to speculate as to what might happen if the provincial voter absents himself, for we know already what does happen when he is not present. We know that in off-meetings of the College, either for election or debate, the acts of the College are left almost altogether in the hands of the metropolitan Fellows, of whom the professors, lecturers, and grinders are the chief part. On these occasions, as the provincialists have no elective vote to give, they do not come to Dublin, and the result is that it is almost useless to bring forward any proposition which needs their support to carry it.

For these reasons we believe that the introduction of paper voting would be a disaster to the College and to Irish surgery. It would be equally a misfortune for the provincialists themselves, and to the Irish Medical Association and Irish Medical Benevolent Fund, whose influence is maintained by the yearly visit of the provincial surgeons to their meetings.

If, however, so serious a change is to be made, it should at least be done deliberately, and we, therefore, urge that the College ought not to act upon the hasty vote snatched in the scramble which took place at the last College meeting, but should take time to think of the possible effects of the proceeding, and to debate the question deliberately before it decides.

◆

A WARNING TO MEDICAL MEN.

GENERALLY speaking, it is extremely undesirable and unpleasant for medical men to appear in courts of law in vindication of their rights; but there are cases involving matters of principle touching the profession in which this alternative is forced on practitioners, and in which it becomes a matter of public duty. A case of this description came before Sheriff Gebbie, at Dumbarton, on the 19th ult., and the learned gentleman's decision was of so extraordinary a nature that it demands at our hands a passing notice. The facts, briefly put, are as follow:—On the morning of October 9th, 1882, between 7 and 8 o'clock, the medical attendant of a family then residing in Glasgow was summoned to their house by one of the family. Two messages came, the first being received by the housekeeper, and the second by the doctor himself, the messenger, a boy of between seven and eight years of age, representing, though this did not come out in evidence before the Sheriff, that "mother says he (the doctor) is to come quickly." On arriving at the house, a servant girl is found to have been just delivered of a child. The doctor attended to her wants, and made visits subsequently until her removal from the family. He is not informed that his attendance on the case is under any exceptional form of contract, and he attends solely on the credit, as formerly, of the family. A bill for this attendance being incorporated with the family account at the end of the year, payment of it is refused on the ground that the master did not employ the doctor, and it was to enforce payment of this claim that the latter sought redress before the Sheriff-substitute of Dumbartonshire. Proof being led, it was not denied that the doctor attended; it was not denied that the master's boy went twice for the doctor; but the liability was sought to be evaded on the ground that it was the servant herself who sent the boy for the doctor—a servant who, by the way, could hardly have known that this particular practitioner was the family attendant, as he had *not been* professionally or otherwise in the house since she entered it as a servant. It was admitted by the mother that she was present when the boy was asked to go for the doctor, but it was maintained by her, as already stated, that the order to go for the doctor proceeded not from her, but from the servant. On this representation, the Sheriff found for the defendant, the doctor being told that he had recourse against the servant, or the father of the child, of whose names and whose whereabouts he was in complete ignorance. Now, we cannot help regarding this as an extraordinary decision, and one to which we invite the attention of the profession. In arriving at this conclusion, the Sheriff-substitute seemed to have considerable doubt in his own mind, for he openly in Court solicited the opinion of Mr. Maclachlan, Town Clerk, of Helensburgh, whose view of the question favoured the doctor. Sheriff Gebbie, however, we understand, has an exaggerated veneration for print, and Fraser's book on "Master and Servant" being produced, and the following passage read, he quickly arrived at the conclusion stated. The passage referred to is as follows:—"With respect to servants, the rule seems settled that the master is not bound to call in a surgeon, even where the injury was sustained in doing the master's business; and if the servant do so himself, *without the master's knowledge*, the latter is not liable for the surgeon's bill. But if the master interfere, a contract may be inferred, so as to subject him to liability for the medical attendance; and in that case he could not deduct the amount of his payment from the wages; and if *a servant become ill and the master call in his medical man to attend such servant*, the master will not be allowed to deduct the charge for medical attendance from the servant's wages, unless there is a special contract to that effect." Now, with every respect for the Sheriff-substitute of Dumbartonshire, we submit that this is the law as bearing on the contract between *master and servant, but not as between master* as his *usual medical attendant.* Here, as in every other case, facts and circumstances ought to be taken into account. It was on the credit of the family that in this case the doctor rendered services to a person of whose name even he was in ignorance; he received the message from one of the family; the mother confessed to having been present when the order to go for the doctor was given, and surely if the idea were then entertained of denying the liability of employment the doctor should there and then have been informed that his attendance had not been requested in his capacity of usual medical attendant. In this case, the Sheriff-substitute gravely informed the doctor that on receiving the message he should have satisfied himself by whom he was being employed, and to whom he was to look for payment. Now, in the name of wonder! how could it ever occur to a doctor, under the circumstances, to surmise that there was anything unusual in the form of contract? Of the mysteries of law we confess to but a limited acquaintance, but it is seldom difficult to see that law is based upon common sense, and is the impartial arbiter and dispenser of justice. Sheriff Gebbie's decision appears to us to be neither the one nor the other, and his conclusions are such as to be spurned and resented by the medical profession.

◆

Notes on Current Topics.

The Coming Election at the Royal College of Surgeons of England.

THE annual election of members of Council, which takes place to-morrow (Thursday) is looked forward to with more than ordinary interest. Owing to the retirement by rotation of Mr. Prescott Hewett, Mr. Birkett, and Mr. Cooper Forster, there will be three vacancies to be filled. Of these, Mr. Cooper Forster alone seeks re-election, and will, without doubt, meet with the success he merits. Yet we must caution the Fellows not to be too confident of the success of any candidate where so many are in the field as on the present occasion. Many a place has been lost because a number of voters, relying upon an assured success of some particular individual whom they have been desirous of re-electing, have bestowed their favours upon others whose chances were not considered so good. Provided Mr. Cooper Forster be re-elected, there are yet two vacancies, for which the following candidates have applied, named in the order of the date of Fellowship:—Messrs. Sydney Jones, George Lawson, Arthur Durham, Brudenell Carter, Reginald Harrison, Sir William MacCormac, Oliver Pemberton, and Charles Macnamara. Though perhaps every one of these gentlemen would make excellent members of the Council, yet not one can claim any right in virtue of eminence or special scientific position to supersede others who obtained their Fellowship at an earlier date. The first two in order of date of Fellowship are Mr. Sydney Jones and Mr. George Lawson, and we trust, therefore, that in all fairness these gentlemen may be elected.

The Princess Alice Memorial Hospital.

ON Saturday last that pleasant and prosperous health resort, Eastbourne, was *en fête* to welcome their Royal Highnesses the Prince and Princess of Wales, who had promised to formally open the Memorial Hospital, which has been erected by voluntary effort to perpetuate the memory of the Princess Alice in the town, where she spent some few weeks of the last of her life. The town was as gay as loyalty, art, and money could make it, and the reception accorded to their Royal Highnesses was of a most flattering and enthusiastic description. The pleasure, however, was not untinged with sadness as reference was made, both by the Prince of Wales, Lord Hartington, and other speakers, to the void occasioned by the death of the Princess Alice, and the presence there that day of Her Royal Highness's daughter, in very feeling terms. The new hospital is a wise and practical outcome of public loyalty, and we join in the noble speaker's heartiest wish for its perpetual prosperity.

The Health of Dublin.

THE report on the state of public health in Dublin for May, by Dr. Cameron, Superintendent Medical Officer of Health, says that the deaths within the metropolitan registration area amounted to 1,003 during the five weeks ended 2nd June—30 per 1,000 persons living. The deaths within the city registered were 777, and were in the annual ratio of 32·26. The deaths from the seven principal zymotics were, in the whole registration district, in the ratio of 2·74. As compared with the preceding month, the deaths from typhoid fever and diarrhœa decreased considerably. There was an increase in the number of deaths from simple fever. The deaths from typhus fever and whooping-cough were about the same. The zymotic death-rate decreased from 3·37 to 2·88 per 1,000 persons living. As compared with the previous month there were decreases in the number of admissions of persons affected with typhoid and typhus fever cases, and an increase in the admissions of persons affected with scarlet fever.

State of Public Health in May, 1883.—The death-rate was higher than during the corresponding periods of 1881 and 1882, but it was much lower than the May of 1880 and of 1879. The zymotic death-rate was slightly larger, as compared with the May of the two preceding years, but it was less than one-third of zymotic death-rate in May, 1880. The early part of the month was very cold for the season, and the deaths from diseases of the breathing organs were above the average of the corresponding period of the previous decade.

The West London Medico-Chirurgical Society.

THE members of this society dined together on Thursday, June 14th, at the "Star and Garter," Richmond, Dr. E. Hart Vinen, in the chair. The usual loyal and other toasts were drunk and in proposing the toast of the evening, namely, "Success to the Society," the chairman congratulated those present on the prosperity of the society, on the favour with which its formation had been received by the medical men of the district, on the steady increase in number of members, on the character of the papers, on the enthusiasm of the discussions, on the attendance at each meeting, on the state of the finances, and on the prospect for the future. A very pleasant and social evening was passed, to which the charms of the *locale* and the beautiful weather greatly conduced. Thus was brought to a close the work of the first year of the society's existence, which to quote at second hand from the *menu*, latinised by Dr. Vinen, was "*ab ovo usque ad mala*," a thorough success.

A Fever Hospital for Oxford.

The question of providing Oxford with a special fever hospital, which has been several times the subject of considerable discussion, is at length decided so far that the town is to possess such an institution at an early date. The site chosen for the building is hardly such as would commend itself to the most exacting architect, seeing that it is subject to flooding so long as the river possesses its present configuration. Certain alterations and improvements in connection with the stream are in view, and when completed the proposed hospital will stand about six feet higher than the greatest known flood level, and be thus, it is assumed, all that an infectious hospital can desire to be. Oxford, it must be admitted, is peculiarly situated, so that it would be difficult to select an available site for the proposed hospital within a short distance of all parts of the city; and, under the circumstances, any more satisfactory position than that which has been selected it would be difficult to find. It is a matter for congratulation that any chance at all presents of obtaining so much needed an improvement for the place, the benefits to be derived from which cannot be readily over-estimated.

The Baly Physiological Medal.

The annual election of Baly Medallist has this year resulted in the distinction being conferred on Dr. Brown-Séquard, on whose behalf Dr. Pitman was presented with the prize on the conclusion of Dr. Habershon's Harveian oration last Wednesday. This medal is named after its founder, the late Dr. Baly, who instituted it as a distinction in physiological science, to be awarded on the choice of the Royal College of Physicians of London. It may be remembered that the medal was presented to the late Charles Darwin, just three years ago, a fact referred to by Dr. Habershon in the course of his address.

Death of Mr. Spottiswoode.

A universal feeling of regret in scientific circles throughout the world will be aroused by news of the death of Mr. Spottiswoode, President of the Royal Society of London, which occurred on Wednesday morning last. The deceased *savant* had been ailing for some time, and an attack of typhoid fever, from which he had not sufficient strength to rally, brought about the sad termination by which a most active and pre-eminently useful life has been cut off at the early age of fifty-eight years. The versatility and acute perception of the late President of the Royal Society have long received wide recognition and respect, and have enabled him to exhibit more than a passing interest in subjects of scientific importance of which he had not made exhaustive study. His unceasing devotion to the duties devolving upon him in his official capacity has doubtless contributed to the loss sustained by his decease. The labours he has accomplished, however, and the memories he leaves will form an enduring memorial of one who has manfully upheld the dignity of British science and the authority of research.

The Royal Commission on Sewage.

It is generally understood that the Royal Commission on Metropolitan Sewage Discharge are now approaching the close of their labours, having concluded the reception of evidence respecting the effect of the drainage outfalls on the sanitary condition of the Thames. The next meeting of the Commission is fixed for Monday next, when the final speeches of Counsel will commence. Unless the Commissioners think it necessary to enter on a further inquiry, with a view to discover some improved plan for disposing of the sewage, it appears not unlikely that their Report will be presented at an early date—probably, before the rising of Parliament.

The Predictions of a Murderer.

A correspondent sends us the following extraordinary statement, which, if founded on fact—and he has the authority of the American and Parisian press—has also the merit of continuity in coincidence:—

It is well known that Guiteau, the assassin of President Garfield, when upon the point of being condemned, made a prediction of sundry recompenses which would fall upon those who had contributed to his condemnation. Struck by a powerful malediction, its effects would promptly overtake them. That prophecy, says our correspondent, is being accomplished with startling rapidity. The wife of the attorney of the Corkhill district, who displayed so much ardour in the pursuit of Guiteau, died immediately after his condemnation. So died Surgeon-General Barnes, whose deposition was most hostile to Guiteau. Dr. Noble Young is also dead. Porter, the judge, whose "charge" was so violently pronounced against the criminal, is in shattered health, and incapable of duty. The marshal Henry, the bailiff Stahl, the detective McElfresh, Perry Corson the guard, and James Leonard the prison coachman, are destitute. The Rev. Mr. Hicks is pursued by defamation. Dr. Grevy has been killed in an asylum for the insane. Dr. McDonald is troubled on account of his administration of Ward's Island, and is the subject of Government inquiry. The sergeant Mason has been for a long time in prison, while his wife and a lawyer are fighting over some thousands of dollars subscribed by the enemies of Guiteau. The wife of one of the jurymen (Hobb) has died, and the juryman Mike Scheban has been struck by madness. Thus ends for the present this "tale of woe."

The Professorship of Anatomy in Dublin University.

The election to the Professorship which has been vacated by Dr. MacAlister, on his appointment to the Anatomical Chair at Cambridge, will take place on the 29th of September. The Board of Trinity College will make the choice, which, however, must be approved, *pro forma*, by the College of Physicians. The title is that of Professor of Anatomy and Chirurgery, and its scope is rather within histology than pure anatomy.

"The emoluments consist in a fixed salary of £250 per annum, and of fees of three guineas, payable by each student attending clinical lectures delivered by the Professor in Sir Patrick Dun's Hospital.

"The Professor is also entitled to the lecture fees, the amount of which is liable to be regulated from time to time by the Provost and Senior Fellows. He is also entitled to a portion of the profits arising from the dissecting room."

The candidature, at present, lies between Dr. Thomas Evelyn Little, who has held the office of University Anatomist in the same school for many years, and Dr. D. J. Cunningham, the distinguished Professor of Anatomy and Physiology in the Irish College of Surgeons, formerly an assistant to Professor Turner in the University of Edinburgh.

The free competition for this most valuable Professorship is limited by the absurd regulation which requires the professor to deliver clinical lectures in Sir Patrick Dun's Hospital, a function which no anatomist worthy of the position would willingly undertake, or would be competent to discharge. If these clinical lectures are delivered, and are worth listening to, they must be given by a practising surgeon, who is obliged to substract from his anatomical work much time and brain labour which ought to be devoted to it. If they are not worth listening to, then it is discreditable to both University and hospital, and a great hardship on the student to compel him to pay for and attend them. We hope some day to see the Senate of the University take up this matter and put a stop to the system of spoon-feeding Sir Patrick Dun's Hospital by compelling University medical professors to act on its staff.

Snake Poison.

Drs. Weir Mitchell and Reichert have recently published some interesting facts relating to the venom of serpents. They find that all the venoms they have examined present certain characteristics in common. They are invariably of acid reaction, and, when dried, soluble in water, save for a slight cloudiness. The authors do not find an alkaloid in any of them, but in every case the poison appears to be made up of three distinct proteid bodies. The first, which they say is a peptone, is less active than the combined poisons, but reduces the blood pressure, induces œdema, and finally produces putrefactive effects. The second is an extremely virulent substance, 1·20th of a grain being sufficient to kill a strong pigeon in two hours; it gives rise in a few minutes after injection to enormous infiltration of blood into the neighbouring tissue. The third is doubtfully poisonous.

Lord Wolseley, who is an Irishman by birth, was on Friday last presented with the honorary degree of LL.D. in the Examination Hall of Trinity College, Dublin, in presence of a large and distinguished assembly of the nobility, the clerical, medical, and legal professions.

From the official returns made to the Registrar-General, of the relative mortality of the principal large cities in Europe, America, and India, it appears that London still occupies the first position for healthiness. Last week its death-rate was but 17 per 1,000 of its population of 3,955,814. Whereas Paris, and New York had a death-rate of 25, Vienna 29, Berlin and Rome 31, and Prague 43 per 1,000.

Insanity in a Child.

The *Alienist and Neurologist*, April, 1883, says that a six years ten months' old child is reported by Berner (*Norsk Magazin for Lægevidenkaben*, Bund XII., Hefte 3) to have been attacked by melancholia. The patient was desirous of solitude, very restless and unquiet in slumber, and had hallucinations of sight and hearing. There were at times paroxysms of markedly painful depression. Hereditary history was uncertain, and the patient recovered in a month.

Medical Society of London.

A conversazione was given at the rooms of the Medical Society, under the presidency of Sir Joseph Fayrer, on Monday night. Among the guests were the Prince of Wales, Prince Lucien Bonaparte, Earl of Selkirk, Sir Bartle Frere, Sir Richard Temple, Sir James Hanbury, Sir W. Robinson, Director-General Reid, Canon Duckworth, and many eminent members of the medical profession. The band of the Grenadier Guards was in attendance. The rooms of the Society, which were decorated with taste and ornamented with flowers and tropical plants, have been almost entirely rebuilt. They are very handsomely arranged, and libraries, refreshment rooms, lavatories, &c., have been added. The President and Secretaries are to be congratulated on a very successful entertainment.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 35, Bombay 27, Madras 28, Paris 25, Geneva 19, Brussels 26, Copenhagen 24, Stockholm 26, Christiania 20, St. Petersburg 33, Berlin 31, Hamburg 27, Dresden 25, Breslau 35, Munich 37, Vienna 29, Prague 43, Rome 31, Turin 29, Venice 23, Lisbon 31, New York 25, Brooklyn 19, Philadelphia 19, Baltimore 19.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Leicester 12; Norwich, Brighton, Bristol, Bolton, Portsmouth 14; Wolverhampton, Bradford 15; Plymouth, Cardiff, Nottingham, Birkenhead 16; Salford, London, Edinburgh 17; Halifax, Newcastle-on-Tyne, Oldham, Derby 18; Birmingham, Sunderland 20; Hull, Sheffield 21; Leeds, Preston 22; Manchester, Blackburn 23; Huddersfield 24; Liverpool, Dublin 25; Glasgow 29.

The highest annual death-rates from diseases of the zymotic class in the large towns last week were—From scarlet fever, 1·4 in Manchester, 1·8 in Leeds, and 3·0 in Sheffield; from whooping-cough, 1·2 both in Hull and Birkenhead, and 1·4 in Liverpool; from "fever," 1·2 in Birkenhead, and 1·3 in Liverpool; and from diarrhœa, 1·0 in Blackburn, and 1·1 in Preston. The 22 deaths from diphtheria included 12 in London, 4 in Glasgow, and 2 in Liverpool. Small-pox caused 2 deaths in London and one in Newcastle-upon-Tyne.

The Medical Bill.

On Friday, June 22nd, a deputation from the Irish College of Surgeons waited on Mr. Mundella, M.P., at the Privy Council Office, by appointment, to submit the amendment of the Medical Bill which the College considers indispensable. The deputation consisted of the President, Mr. Wheeler; the representative of the College in the Medical Council, Mr. MacNamara; Mr. Barton, and Dr. Jacob; and the suggestions offered to Mr. Mundella were embodied in the statement of which we published the chief part in our last issue.

The College asks for—*a*. Uniformity of the curriculum required for the Medical Board examinations throughout the Kingdom. *b*. That the scheme of examination and education be made by the Medical Council and sent to the Medical Board to be carried into effect, and not, as proposed by the Bill, made by the Board and sent to the Council to be revised. *c*. That no University student shall be entitled to exemption from the full examination fee unless he be an Arts graduate or an Arts undergraduate of 3 years' standing. *d*. That the surplus funds arising from examination and registration fees be allocated equitably to the three divisions of the Kingdom, in proportion to the medico-educational work done therein. *e*. That in the Medical Board for Ireland the Colleges should not have a less representation than the Universities, and that the direct representative for Ireland should have a seat on the Irish Medical Board.

Certain other amendments of minor importance were also submitted.

Mr. Mundella received the deputation in an unyielding spirit, and contested each of the proposed amendments in detail except that with reference to the fees payable by University students, to which he gave a modified assent. As to the *locus standi* of the direct representative, Mr. Mundella considered his admission to the Medical Board to be absolutely inadmissible, and that if entertained by the Government, would be fatal to the Bill. He seemed to be under the erroneous impression that the profession at large is entirely satisfied with the Bill in all its details, and with the function given to the direct representative under it, and to anticipate a violent opposition to the proposition from some unknown quarter, and he referred to the petition presented by members of the British Medical Association as proof that the profession was anxious to accept the Bill unreservedly and without amendment, and did not regard the position of the direct representative as of critical importance.

Having thus failed to impress Mr. Mundella with its views, the deputation decided to submit its arguments to the members of the House, and immediately proceeded to organise a conference of M.P.'s for Tuesday, the 26th. That conference was attended by twenty-four members, including Messrs. Gibson, Plunkett, King-Harman, Mitchell Henry, Drs. Cameron and Farquharson, Viscount Crichton, Captain O'Shea, Mr. Ellison, Mr. McCartney, Mr. Callan, Sir Lyon Playfair, Mr. Corry, Mr. Findlater, Mr. Mulholland, Mr. Biggar, and other influential members.

The views of the College were very fully put before the conference, and heard with the most intelligent and careful consideration by the assembled members, and the deputation retired much gratified with the reception which their observations had met with.

Since the return of the deputation to Ireland the College of Surgeons has followed up the steps already taken, and is ready to submit its amendments and enforce them by its entire Parliamentary influence when the proper time comes.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

The Scottish Universities and the Medical Act Amendment Bill.—The Scottish Universities have issued in pamphlet form the speeches of their recent deputation to the sorely tried Lord Advocate. It is needless to say that we regard the pamphlet as altogether a weak production, and that this struggle for money, and the dread of fair and open competition manifested by the Scotch Universities is highly discreditable to them. As to the Divisional Board, the chief bone of contention, we have already pointed out that their desire for strength upon it is to correspondingly preserve the teaching monopoly. As a matter of fact, it is the opinion of unbiased members of the profession that *no teachers whatever* should be on the Divisional Board; that the State should institute a minimum examination totally independent of the Universities and Corporations, and that it would be a generous act on its part to allow them to retain the right of giving their "higher" qualifications to whomsoever desired to possess them. So long as the Universities have any control over the passing of men into the profession, so long will their pernicious monopoly remain, and "medical reform" will be a mere farce. The Scotch professors figure in a most undignified manner in throwing mud at the Corporations, and at the University of St. Andrews, in the unworthy hope that from this ordeal the virtues of the three great educational trade-protection institutions of Scotland will shine forth more conspicuously. We boldly assert that no case has been made out against the Corporations of Scotland which does not equally apply to the Universities; and from what we all know of the Universities of Scotland, is it for a moment to be supposed that their professors are proof against their *decided pecuniary interest* in passing men into the profession? In all probability we shall have to be content with an instalment of justice merely, as reform of all kinds is slow, and as money rights are fought for no less furiously by philosophers than by beings of a meaner order. (*Vide* the columns of the *Glasgow Herald passim*).

The Partick Poisoning Case.—Robert Craig, druggist's assistant, Partick, was apprehended on Tuesday, the 26th ult., on a charge of culpable homicide in connection with the death of George Mackay, as reported in the *Medical Press* of June 26th, who died through a poisonous drug being dispensed to him from the prescription of a Glasgow surgeon. After the taking of formal evidence the case was adjourned, bail being accepted for £50.

The University of Edinburgh.—For the final examinations now being held there are no less than 240 candidates. We also learn that one of the extra-academical examiners has begun to show signs of home-sickness, and does not appear to relish a residence of three weeks away from his London practice. Before accepting the post he should have made inquiries as to his duties; and he must, for this occasion at least, exercise some amount of that Christian resignation for which we believe he is much renowned.

Health of Edinburgh.—For the week ending with Saturday, the 23rd ult., the mortality in Edinburgh was 70, and the death-rate 16 per 1,000. Diseases of the chest accounted for 38 deaths, and zymotic causes for 4, of which 1 was due to scarlatina and 1 to measles, the intimations of these diseases for the week being 15 and 52.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 23rd ult., were at the rate of 30 per 1,000 per annum, against 30 in the preceding week, 25, 22, and 24 in the corresponding periods of 1882, 1881, and 1880.

SUDDEN DEATH OF DR. JAS. MOIR.—On Friday morning, Dr. James Moir, of Aberdeen, died suddenly at the railway Station of that city, under peculiarly painful circumstances. Dr. Moir had arranged to accompany the Aberdeen Association of Chemists and Druggists on the occasion of their annual excursion, a short distance into the country. Fancying himself late for the train he hurried to the station, and was so overcome on reaching it that he complained to his friends of giddiness. He was assisted into the station refreshment rooms, where he died in a few minutes from apoplexy. The deceased had been in weak health for some time past. Dr. Moir, who was 65 years of age, was a native of Aberdeen. Early in life he followed his profession in Alyth, but for many years past had been located in Aberdeen, and he had an extensive practice among the poorer classes of society. The occurrence naturally cast a gloom over the pic-nic party, by whom the excursion was abandoned.

OUTBREAK OF MEASLES IN THE FAIR ISLE.—News has been received at Lerwick that measles has broken out in Fair Isle, situated midway between Orkney and Shetland. The disease is very prevalent, and has attacked in some instances five out of six persons in one family. It is thirty years since measles last appeared in Fair Isle.

PROFESSORS LEISHMAN AND BELL PETTIGREW. — Dr. Leishman replies in the following terms to the remarks of Dr. Bell Pettigrew, of St. Andrews, referred to in our last impression :—I beg Dr. Pettigrew's attention to the fact that the tatements he complains of were first made a week before I spoke, at an interview with the Lord-Advocate in London. At that meeting reporters were present ; the statements appeared in every leading journal in Scotland ; and these statements remained unchallenged by Dr. Pettigrew or anyone else. That might be my excuse for any inaccuracy, did such exist ; but, so far from Dr. Pettigrew being able to point out any, I think he supplies, by implication at least, the strongest corroboration of almost all that Dr. Gairdner said in London and I repeated here. I stated—as reported, and, I believe, correctly reported, by you—that "St. Andrews gives in the course of the year, under certain special conditions, to men already on the Register, a certain number of degrees. I think I am correct in saying that, during the last ten years, the University of St. Andrews has placed five men on the Medical Register." To this Dr. Pettigrew replies that in that time they have "made 110 doctors of medicine." Of course they have, but these are the very men who are made doctors on the special conditions to which I distinctly referred, and Dr. Pettigrew does not contradict my statement that they have only placed five men on the Register in ten years. Nay, in point of fact, I believe that the number is less than five, and that, in my anxiety to avoid the slightest exaggeration, I have actually understated my case. Your correspondent objects, further, to the inference I draw that the St. Andrews vote on the Scottish Board could under no circumstances be counted for the Universities. That it would be given "in the interests of right and justice" I do not for a moment doubt, but at the same time I do not think it is any exaggeration—knowing that the University of St. Andrews has but a fragmentary medical faculty, no medical school, no hospital, and an infinitesimal interest in graduation—to say, as I have said and now repeat, that it "has no interests whatever in common with the other Universities," with their medical graduates counted by hundreds and their medical students by thousands.

THE WORK OF EXAMINERS.—At present there are between 230 to 240 candidates for the final examination in the University of Edinburgh. On each subject there are but two examiners, so that it may be conceived that the time of the examiners is well occupied. It may well be questioned if justice can be done to the candidates, and if it is not more than human nature can support to be engaged for two or three weeks examining for four hours continuously every day. Besides, we believe that the written papers have to be examined and marked in 24 hours. How can this be done with justice to the examiner and candidate?

ROWDYISM BY STUDENTS AT THE EDINBURGH THEATRE ROYAL.—We regret to state that the Edinburgh students have again been distinguished by highly unbecoming conduct at the Edinburgh Theatre Royal. In the course of a performance by Miss Palmer, a talented young American actress—who, we fear, must have formed strange impressions of Scotch students—a scene of riot and ill-mannered buffoonery ensued. These gentlemanly youths yelled and mimicked actors and actresses alike. With their pockets loaded with peas and gravel, they pelted the occupants of stalls and stage, until, becoming enraged, the other occupants of the gallery set upon them, and a free fight followed. Ultimately nine of them were arrested and lodged in the police-station for the night, and the performance was allowed to proceed after a delay of twenty minutes.

Literature.

BUXTON AS A HEALTH RESORT. (a)

IN this little work Dr. Thresh has done good service by disposing of the error about the quantity of nitrogen which previous analysts had circulated. We have always regarded Muspratt's and Playfair's statements on this point as incredible, and are glad to see a series of careful investigations into the chemistry of Buxton water. It is not every spa that can boast of a resident D.Sc. Lond., and we hope Buxtonians duly appreciate their able townsman. Not only is the nitrogen question settled by Dr. Thresh's labours, but he gives us new analyses of the waters, and an account of the mud deposited where it issues from the earth. After all, it appears that Buxton is richer in nitrogen than Wildbad or Gastein, the two springs it most resembles. It is, perhaps, natural for the author to attach importance to this gas, and he hints that it escapes in what may be thought a semi-nascent state from solution in the water. We do not ourselves think the nitrogen of therapeutic import, regarding temperature and mode of use, with other circumstances, as the agents of cure. Buxton maintains its position, and the hospital records show that the waters are efficacious in arthritic ailments. Whenever a thermal water of only 80° is indicated, with bracing mountain air, Buxton may be trusted. But the climate is rather bleak, and those patients who are very sensitive to cold may find it trying. Those, however, who can bear the bracing cold will find it a powerful tonic. Dr. Thresh gives also a sketch of the town, its position, water supply, sanitary state, &c. The rate of mortality is very low, and the "Queen of the Peak" should attract an increasing number of visitors, who can explore the neighbourhood on foot. As to the baths, we should like to see them enlarged and improved. It is a pity that English spas are not as thoroughly worked as foreign ones. There is room for fresh outlay, and the lord of the manor ought to look to this. Then, too, there is a want of accommodation which he might well supply. Surely the rich Duke of Devonshire might incur more outlay, which would be sure to add to his wealth. A few years ago we were in Buxton, and then we deeply regretted that more was not done to keep it in the front rank of spas. It is this apparent inability of the English to carry out what is most required that drives so many from British to foreign resorts. We hope the publication of Dr. Thresh's excellent work will serve as a stimulus to the lord of the manor and all else whom it may concern.

(a) "Buxton as a Health Resort." By J. C. Thresh, D.Sc. Lond., F.C.S. Buxton: Wardley. 1883.

Correspondence.

THE RECOGNITION OF FOREIGN DIPLOMAS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your remarks upon the petition presented by Mr. Mundella to the House of Commons on behalf of foreign graduates practising in England are likely to mislead your readers. Either you cannot have carefully read the petition, or else must have entirely misunderstood its purport. The petitioners did not pray for the recognition of all foreign degrees indiscriminately, as your remarks would infer, but for the registration of all respectable foreign degrees obtained after thorough examination by men already registered under the Medical Act. The worthless degree referred to by you as an example of what kind of degrees might possibly find their way to the Register if the petition of the Foreign Graduates' Association were acted upon is exactly one of those degrees which will have a right to admission to the Register under the new Act as it at present exists, whilst the degrees of Berlin, Bonn, Göttingen, Giessen, Heidelberg, and Brussels will be left out in the cold. You ask how I would suggest that the Medical Council might discriminate between one degree and another. By registering all European and Colonial degrees I think they would not do much harm, as any of these will most favourably compare with the degrees of some of our own universities. In the United States and other American Republics great care would be required to discriminate between worthless and honourable degrees, as some of their universities—for instance, Harvard, Pennsylvania, New York, and Jefferson—are highly honourable, whilst others are just the reverse. You must be aware of the fact that no European university of the present day grants medical degrees without thorough examinations being passed, equal in every respect to the examinations of this country. This is beyond dispute, and may be proved by any one who will take the trouble to inquire. The old cry of "bogus Continental degrees" which now and again is heard is but the outcome of that ignorance of the customs of foreign countries, and of that insular prejudice and vanity so often met with in this country, which is productive of no good, a great amount of ill-feeling, and much amusement to foreigners, who, as a rule, look upon us as a vain and bragging people.

I am, Sir, yours, &c.,

H. J. HARDWICKE, M.D.

Sheffield, June 27th, 1883.

[We are not by any means satisfied that all Continental degrees are above suspicion even when stated to be conferred on examination, and, therefore, it seems to us prudent that the Medical Council shall not register the holder of any of these degrees unless he can also produce the "Staats examen" certificate or other official evidence that he is up to standard in point of education. To register such degrees would be to give to an institution of which little is known and which cannot be inspected, privileges which are refused to home licensing bodies whose examinations are tested and certified. The foreign diploma clauses of the Bill are very unsatisfactory in one respect. They empower the Medical Council to recognise—of its own pure discretion—any foreign or colonial degree it pleases, and for ever afterwards all holders of that degree will be registered *ipso facto*. Lord Ripon's Bill, on the contrary, required that the individual seeking registration should satisfy the Council that his foreign degree was up to the home standard, and each individual would be dealt with separately.

When we look back upon the wholesale recognition by the Medical Council of preliminary education certificates issued by foreign and colonial bodies we may well apprehend a wholesale recognition of analogous professional education certificates without inquiry or vigilance if the Medical Council is authorised to accept them at its own unlimited discretion.

Dr. Hardwicke has not yet attempted to tell us how the Council should discriminate between good and bad, and we wait his solution of the difficulty.—ED.]

◆

THE IRISH MEDICAL BENEVOLENT FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would have appeared ungracious if any one had expressed disapproval of the observations of the ex-President of the College of Surgeons at the close of the annual meeting of the Medical Benevolent Fund Society, when thanking those present for the usual vote of thanks to the presiding chairman. I hope, however, that silence upon that occasion may not be misunderstood, and that it should be supposed that many approved of the idea of putting begging-boxes in our studies or consulting rooms to tax poor persons, from whom we would not accept fees, and tacitly ask them to aid in supporting an institution which we have a right to support ourselves. I hope we shall never have this idea put forward again. It will of course appear in our next report as part of the speech of the ex-President of the College of Surgeons, but after that I hope it will be "buried in the tomb of the Capulets," and that no attempt will be made to resuscitate it.

I am, &c.,

AN OLD SUPPORTER OF THE MEDICAL
BENEVOLENT FUND SOCIETY.

◆

Medico-Parliamentary.

HOUSE OF COMMONS.—FRIDAY, JUNE 29TH.

THE CONTAGIOUS DISEASES ACTS.

THE Marquess of **HARTINGTON** asked leave to introduce a Bill to provide for the detention in certain hospitals of persons afflicted with contagious diseases and to repeal the Contagious Diseases Acts 1866 and 1869. The Bill, he said, would proceed on the analogy of the Poor Law, and would give power to detain persons affected with contagious diseases in certain certified hospitals. The provisions relating to examination, registration, and the so-called voluntary submission to examination would be repealed. He regretted that the House had declined to continue longer the experiment tried by these Acts, but there was no doubt a strong feeling in the country on the subject.

Mr. **PULESTON** remarked that the Bill would be practically worthless.

Mr. **WARTON** suggested that the knowing or negligent communication of disease should be made a misdemeanour.

Leave was given to introduce the Bill, and it was read a first time.

THE OUTBREAK OF CHOLERA IN EGYPT.

Mr. **CARTWRIGHT** asked the Under Secretary of State for for Foreign Affairs whether there was any official information as to the character of the epidemic which was reported to have broken out at Damietta, and of the number of deaths that had already occurred; and also to the appearance of the epidemic in other localities besides Damietta.

Lord E. **FITZMAURICE**.—I regret to say that the reported outbreak of cholera at Damietta has been confirmed by intelligence received from her Majesty's Consul at Alexandria, and up to yesterday about 180 deaths would appear to have taken place. Cases have also been reported at Mansourah and Port Said; but no cases have as yet appeared amongst British troops.

THE MEDICAL STAFF IN EGYPT.

Viscount **FOLKESTONE** asked whether there was with the British troops in Egypt a sufficiently large staff of medical officers, and a sufficient supply of medicine to cope with the possible outbreak of cholera.

The Marquess of **HARTINGTON** replied that there was a sufficiently large staff of medical officers in Egypt to meet all probable requirements, and a reserve was in readiness to proceed there if necessary. The supply of medicine was adequate, and an addition was then in course of shipment of such articles as were likely to be useful in the event of the outbreak of cholera. Instructions had been telegraphed to the general officer commanding in Egypt to take all suitable measures to prevent an outbreak, and his attention had been called specially to Indian regulations on the subject. His

Lordship added that a reply had been received to the effect that those instructions had already been followed, and that there is no immediate fear of cholera among the troops.

WOOD PAVEMENTS AND DISEASE.

Viscount NEWPORT asked the Chairman of the Metropolitan Board of Works if it was not the fact that since the recent extension of wood pavement in the metropolis serious affections of the eyes and lungs had been largely on the increase; and whether it would not be possible to mitigate in some degree this growing evil by a more careful and thorough system of cleaning and washing the streets.

Sir J. M'GAREL-HOGG.—I beg to inform my noble friend that the streets of the metropolis are not under the control of the Board over which I have the honour to preside, and I have no information of the evils he refers to. I cannot speak with any weight with regard to remedial measures, or their necessity, but perhaps my noble friend's question will be the means of directing the attention of the local authorities to the subject.

◆

PASS LISTS.

Royal College of Physicians of London.—The following gentleman was duly admitted Fellow of the College on Thursday last, the 28th ult.:—

Herbert Watney, M.D. Cambridge, 1 Wilton Crescent, London, S.W.

Royal College of Surgeons of England.—The following candidates having passed the required examination, received the diploma in Dental Surgery at a meeting of the Board of Examiners on June 27th:—

Butcher, John Oliver, Brixton.
Duncan, Oliver Gold, Hampstead.
Greetham, Peter William, New Wandsworth.
Hooper, Gordon, Exeter.
Kirby, Alexander, Bedford.
Nehmer, Ferdinand, Berlin.
Paterson, William Bromfield, M.R.C.S., London.
Richards, Frederick William, Edgbaston.
Rose, Charles, Liverpool.
Segar, Frank, Newton Abbott.
White, Thomas Harry, M.R.C.S., Lincoln.

◆

Notices to Correspondents.

MR. WILSON (Liverpool).—In our hands the liquor santal. flav. c. buchu et cubebâ, Hewlett, has been of signal service in some obstinate cases.

A CANDIDATE.—These appointments are always made for a definite period, renewarble at the discretion of the committee. There is never any difficulty on this point, if the duties of the office have been satisfactorily discharged.

DR. W. G. BLACK (Edinburgh).—The MS. is accepted, and will appear in an early number.

MR. FENTON.—Ruspini's balsamic styptic is well known in this country; its success has been chiefly in hæmorrhage of the lungs. We believe it is obtainable at the principal wholesale druggists'.

INFAMOUS CONDUCT IN A PROFESSIONAL RESPECT.—With reference to the letter of "Alpha" on this subject, we are in full sympathy with him. The "job" perpetrated was of the worst possible class, and at the time we gave it our most strenuous opposition. As, however, the gentleman referred to is in possession of the post, it would be ungenerous to revert to past offences, for which reason we deem it prudent not to publish the letter of our correspondent.

HISTORICUS.—We are afraid we cannot assist you much in your compilation. Westminster Hospital, as is probably known to you, was instituted in 1715. In 1733, Lansborough House was converted into an infirmary by some seceding governors of Westminster Hospital. The old house for many years formed the central part of the hospital, two wings having been added to it when it was converted to its new purposes. Extra wards have since been supplied at a considerable expense, and in process of time the entire building has been reconstructed. From its commencement the hospital has been mainly dependent upon voluntary contributions, not being richly endowed like Guy's, St. Bartholomew's, or St. Thomas's. The present edifice was commenced towards the end of the reign of George IV., by William Wilkins, R.A., ther achitect of the National Gallery, University College, and other important buildings, but several additions have since been made to the original design. There is now accommodation for 215 in-patients; out-patients, 30,000 annually.

DR. PEARSE.—We will look through your papers, and see how they can be best utilised or referred to in the present threatened visitation.

SURGEON-GENERAL GORDON.—We hope to be able to devote space to your "Notes on the History of Epidemics of Cholera" in our next.

SAN FRANCISCO.—There are several medical journals published in the Western States, but the oldest and best known is the *Pacific Medical Journal*, published, we believe, at San Francisco. We are uncertain as to cost of subscription. Any of the foreign houses in London—Baillière's, Trübner's, or Sampson Low's would doubtless give you the information. Your second query would be met by the *New York Medical Record*, the *Boston Medical Journal*, or the *Medical News* of Philadelphia.

THE DIFFICULTIES OF AMERICAN MEDICAL EDUCATION REFORMERS.

THE following is, as nearly as type can reproduce it, a facsimile of a post-card recently received by the Illinois State Board of Health from the President(!) of the St. Louis Eclectic Medical College:—

Fieldon Ill 5-2-12-83.
John H. Rauch MD. Sir you sti-
ll persist in trying to freighten
our Graduates, like Springer of
Hardin, who have attended two
full, long terms in our School &
Honorably graduated. I look
upon you, as the chief, of a set of
Dastard Bigots & villians & the
sooner you arrest Springer the so-
oner you will get through with it.
Yours L C. Washburn. President of
the St. Louis Eclectic Medical College.

The "Dastard Bigots & villians," who compose the Illinois State Board of Health, decline to recognise the St. Louis Eclectic, and "frighten" its alleged graduates by refusing to issue them certificates entitling to practice. *Hinc illæ.—Cincinnati Lancet.*

MEETINGS OF THE SOCIETIES.

WEDNESDAY, JULY 4TH.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Barnes and others.—Dr. Champneys, On the Obstetrics of the Kyphotic, Pelvis.—Mr. Lawson Tait, Note on Uterine Myoma; Three Cases of Pyosalpinx; A Case of Acute Gangrene of the Uterus.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Surgeon-General J. M. Cunningham, On the Sanitary Lessons of Indian Epidemics.

THURSDAY, JULY 5TH.

THE PARKES MUSEUM OF HYGIENE.—At 8 p.m., Mr. Rogers Field, On a Description of the New Drainage carried out at the Museum, with Demonstrations of Sanitary Appliances in Action.

FRIDAY, JULY 6TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8.30 p.m., Annual General Meeting for Election of Officers, &c.—Mr. Snell, On a Case of Recovery from Sympathetic Iritis.—Mr. Swanzy, On a Case of Hemiachromatopsia.—Mr. J. E. Adams: (1) On an Ophthalmoscope for Artists; (2) On a Case of a Foreign Body imbedded close to the Yellow Spot, with Normal Vision.—Mr. Story, On an Anomalous Arrangement of Retinal Arteries.—Living and Card Specimens at 8 o'clock:—Dr. Horrocks, Case of Facial Conjunctival, and probably Retinal, Nævus; Mr. Hulke, Drawing from a Case of probably Intraocular Cysticercus; Mr. Hodges, Melanotic Sarcoma of Iris (living specimen); Mr. Gunn, Case of Congenital Ptosis.

Appointments.

BATT, C. D., M.B. Lond., M.R.C.S., Medical Officer for the Witney District and Workhouse of the Witney Union.

BLIGH, S. E., M.B., C.M. Ed., Medical Officer for the Tooting Graveney District of the Wandsworth and Clapham Union.

COLMER, P. S. H., M.D., L.R.C.P. Ed., L.F.P.S. Glas., Medical Officer for the No. 2 District of the Yeovil Union.

COOMBE, C. F., M.R.C.S., Assistant Medical Officer to the Workhouse of the Sheffield Union.

DAVIES, J. C., M R.C.S., Surgeon to the Ruabon Accident Hospital.

GRANT, D., M.A., M.B., C.M. Ed., Resident Medical Officer to the Manchester Royal Infirmary.

HOPE, E. W., M.D., B.Sc. Ed., L.R.C.P. Lond., Assistant Medical Officer of Health to the City of Liverpool.

MACDONALD, P. W., M.B. & C.M. Univ. Aberd, Assistant Medical Officer to the Dorset County Asylum.

SHEPPARD, W. J., M.B. & M.S. Durh., M.R.C.S., L.R.C.P., Non-resident House Physician to St. Thomas's Hospital.

SHIRLEY, M. B., L.R.C.P., M.R.C.S., House Surgeon to the Worcester General Infirmary.

STEAVENSON, W. E., M.B. Cantab., M.R.C.S., M.R.C.P. Lond., a Casualty Physician to St. Bartholomew's Hospital.

STONEY, G. B. L., Medical Officer to the Lucan Dispensary, Celbridge Union.

STORY, J. B., M.B., F.R.C.S.I., Lecturer on Ophthalmic Surgery to the Ledwich School of Medicine, Dublin.

VINRACE, J. H., M.B. Lond., Assistant Resident Officer at the Hospital for Consumption, Brompton.

WELLS, A. E., M.B. Lond., M.R.C.S., L.R.C.P., House Surgeon to St. Thomas's Hospital.

Births.

HUTTON.—June 27, at 18 West Green Road, Tottenham, N., the wife of Edwin R. Hutton, L.R.C.P., of a son

PLETTS.—June 21, at Wyndham House, Ryde, Isle of Wight, the wife of J. Menham Pletts, M.D., of a son.

MAPOTHER.—June 28, at 6 Merrion Square, Dublin, the wife of E. D. Mapother, M.D., of a daughter.

WRIGHT.—June 22, at 6 Ulverton Place, Dalkey, the wife of W. M. A. Wright, M.B., of a son.

Deaths.

ALLEN.—June 28, at the residence of his brother, Notting Hill, Charles D. Allen, M.B., late of Bagenalstown.

BARKER.—June 26, suddenly, at 3 Milverton Villas, Knowle, Warwickshire, George Barker, M.D., aged 68.

HULEATT.—June 26, at the Adelaide Hospital, Dublin, John A Huleatt, M.D.

JONES.—June 25, at Saffron Walden, Alfred Nicholas Jones, M.R.C.S., aged 62.

SCRIVEN.—June 28, at his residence, 11 Frederick Place, Weymouth, Samuel Swain Scriven, M.D., aged 80.

ON

DISEASES OF THE TONGUE,

DELIVERED AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,

By Prof. JONATHAN HUTCHINSON, F.R.C.S., F.R.S.;

President of the Pathological Society of London; Professor of Pathology in the Royal College of Surgeons; Senior Surgeon to the London Hospital.

LECTURE I.—(*Continued.*)

THERE is yet a third condition in which patches form which may perhaps deserve to be classed as leucomata. Their claim is, however, much less strong than that of the two forms just described, since they are less conspicuous, less white, and not so lasting.

The condition to which I refer is one in which thin pellicular films, closely adherent and not to be removed without bleeding, form on the top of certain groups of papillæ. They are usually coincident with a firm papillary growth, and are seen under various circumstances as regards the patient's health. They are always very small, not bigger than peas, and seldom form round or circular patches, being usually of crescentic form.

The tongue in a state of health is normally smooth on its surface, or at most shows a longitudinal furrow and a few slightly marked transverse ones.

Even in health, however, if the tongue be spread out by the finger, it will be seen if the papillæ are abundant, that they show certain lines or creases as they fall apart.

In all states of disease attended by swelling of the tongue, there appears to be a great tendency to increase their natural furrows, both in depth and width, and we get the condition known as sulcated tongue. The pattern formed by the furrows is by no means always the same, and its peculiarities probably depend upon minor differences in original structure in different individuals.

Sometimes the furrows are most of them more or less transverse, and in others a fluted condition is produced by the development of bossy longitudinal ridges divided by deep sulci. The formation of furrows may be attended by very various conditions of the papillæ.

They may be abundant, even hypertrophied, or they may be wholly destroyed. It is essential that the deeper layers of the mucous membrane or the substance of the tongue itself shall be somewhat swollen, or at any rate, that there shall have been swelling at some former time.

I believe, then, that we may safely take the condition of sulcated or furrowed tongue when unusually developed as proof of present or past glossitis. This remark applies with especial force to the *fluted tongue*, and to all conditions in which furrows are coincident with baldness. There are some curious states of what may be termed ribbed tongue, in which the papillæ are still present, and in which the lines run between them laterally in a branching manner, as if from a mid-rib, in which there is often but little proof of glossitis. This condition of tongue sometimes appears to be simply a personal peculiarity. In another lecture I shall have to discuss its significance more in detail. It is the state for which I have suggested the name fern-frond pattern, a comparison which will, I think, not seem wholly inapt to any one who has an opportunity of inspecting a good example.

Miss G., a lady of about 25, florid, and apparently in fair health, had one of the most thickly furred tongues which I ever recollect to have seen. It was white all over, and at its sides there were patches more dense and smooth than the rest of the surface in which apparently sclerosis was commencing. She said that her tongue had been furred as long as she could remember, and that so far as she could appreciate its condition implied nothing as to her general health. Some years ago she said a surgeon had told her that she was the most foul-tongued young lady he had ever met with. Miss G. consulted me on account of erythematous acne on the chin, cheeks, and forehead. Her bowels were habitually costive, and her feet cold and damp. But except in these matters she ailed nothing. Her brother had once been under my care for palmar psoriasis.

The "parrot's tongue" is a term which was proposed, I believe, by Mr. Clement Lucas, to designate certain conditions of chronic glossitis in which the tongue becomes both bald and dry.

The term is very aptly descriptive of certain states of sclerosis in which there is much denudation and but little thickening. It applies, however, to but a small number of cases; its examples occur chiefly in those in whom the combined influences of superficial syphilitic glossitis and long continued smoking have been at work.

Tongues differ from each other, not only in their surface appearances, but also in their shape and size. Some are flat, large, and flabby, whilst others are narrow, convex from side to side, and pointed.

This latter condition is usually, I think, coincident with some degree of emaciation, and the tongue participates in the general leanness of the body. Not unfrequently, however, a narrow pointed tongue possesses also some surface peculiarities which imply previous disease. Thus the filiform papillæ are almost always deficient in size and number, whilst the fungiform present very varying conditions.

The state known as a rough tongue is usually seen in one that is convex and narrow. Although it is difficult to suggest the explanation of the association.

Flat and flabby tongues are very often indented at their edges by pressure against the teeth. They are usually well clothed with papillæ, and almost always met with in persons in whom the fat and cellular tissue are abundant in other parts. Sometimes, probably indentations from the teeth imply the former occurrence of swelling of the tongue, possibly of a mercurial phi-ptyalism.

I do not know that much is to be said as to the influence of age upon the tongue, other than the general statement that as years advance the perfection of structure diminishes. The number and size of all the papillæ undergo a very marked reduction as age advances and the faculty of taste declines.

Apart from this influence of age as such, we must expect to read on the tongue, in some sense a record of the patients' varying states of heath in former years. So many have at some period of life or other suffered from some one of the various forms of stomatitis that it is not to be wondered at that the tongues of old people should seldom exhibit a perfectly sound condition.

I do not know that I should have had anything to say concerning the black tongue, were it not that it has received considerable attention in France. Amongst ourselves I think it has not as yet been the subject either of description or discussion. *La langue noire*, as the expression is understood in Paris, is not the pigmented tongue of Addison's disease, but one which is more or less covered with a black fur. The particles which give the colour are accumulated in or upon the epithelial scales covering the filiform papillæ. We are all of us familiar with conditions in which the fur, especially that in the middle and posterior parts of the surface becomes dark and, in some instances, quite black; in the late stages of fever this is not infrequently the case, and I believe it is generally correctly referred to staining of a thick adherent fur, either by medicines or articles of food. Cases, however, in which the tongue is uniformly furred black are extremely rare, and much more difficult of explanation.

I have myself seen but one case of this kind, it occurred in a young woman, the subject of the most aggravated hysteria, who had kept her bed for many years, and never spoke, excepting in a whisper. Her tongue was always of a coal black colour over the whole surface. I then thought—and still think—that it was a factitious condition, and this suspicion was confirmed by my finding the tongue almost clean on a single occasion when I paid an unexpected visit. I much regret that I never made a microscopic examination of the fur.

So far as my evidence has yet been accumulated, I should be inclined to suspect that whenever the fur over the whole of the tongue becomes very black, as in my case, that there is some intentional deception, and that the minor cases are still to be referred to accidental causes.

The only example of black tongue which I have ever had the good fortune to see in Paris did not show anything more than might be plainly expected to be accidental, and I am not aware that either models or drawings have as yet been collected. M. Gubler was, I believe, the first to draw attention to this subject, and M. Raynaud, following his suggestion, published in 1869, a note on a parasitic affection of the mucous membrane of the tongue, of which blackness was a symptom. In only one out of five cases, however, did he succeed in proving the presence of spores. These were like those of the tricophyton, and were found in the membrane of the cheek. M. Fereol, in 1875, published a case to prove that the black tongue was not due to a fungus. In his case it affected a man, æt. 40, during convalescence from quinsy, which lasted for a month. Microscopic examination showed the papillæ long and hair-like, and covered with stained epithelium. Monsieur Fereol suggests the name of filiform epithelial hypertrophy, thus clearly supporting the conclusion that the blackness is an accidental concomitant of tongues which have unusually thick fur and long filiform papillæ.

Dr. Lanceraux has described in the *Union Medicale*, No. 33, 1877, some two cases of black tongue with microscopic observations. The blackness was in the usual position, that is, in the mid dorsal region. With the microscope, elongated filiform papillæ bristled over with epithelial accumulation were found, and upon them masses of spores. I do not find any reason for believing that these spore accumulations were other than those which Mr. Butlin has taught us constitute an ordinary element in fur.

M. Armaingaud has observed cases in which black colouration of the tongue occurred in connection with nervous exhaustion in three members of the same family. He also observed it in an hysterical patient. It was removed by the application of oil or glycerine. He suggests an analogy to the obscure and very questionable disease known as chromidrosis of the skin, and believes that it is in association with vaso-motor disturbance. I confess that, so far as his descriptions go, I should prefer to think that in his cases it was accidental, if not factitious.

Dr. Pallarés, of Madrid, has published his own case as an example of black tongue in which the blackness occurred in spots which rapidly coalesced. He examined some scrapings with a magnifying glass and believed them to contain vegetable filaments. The disease was well in a few days, and its real nature must be held to be very uncertain.

M. Vallin, in an observation subsequent to those which I have just quoted, carefully examined a condition of black tongue, which had existed for several weeks, in a man of 60, who had 25 years before contracted ringworm of the beard in Algeria. On the part which was black there were filamentous papillæ so long and abundant that they could be cut off as grass is mown. After repeated microscopic examinations M. Vallin satisfied himself that there were no spores of any kind, and that the condition was only an exaggeration of the mammilous state.

We may dispose of the subject of unilateral atrophy in connection with destruction of the ninth nerve very briefly. Its symptoms are, in the earliest stage—divergence of the tongue when extended towards the paralysed side, and a flabby condition of its muscular substance. Several cases are on record in which the observations were made on the state of the organ at considerable periods after the commencement of the paralysis, and when the wasting was conspicuous. In these the affected half is fissured at its side, and decidedly shrivelled. I have myself had the opportunity of observing one case

---

See "Revues des Sciences Medicales," Tome xi., 1878, Page 185.

in the earliest stage, when, as yet, there was no wasting whatever; and in this case the fact that paralysis existed could only be demonstrated by making the patient put the tongue out, whilst its two halves were held between the finger and thumb of each hand. In this case the paralysis had resulted from a stab in the neck, which had divided the trunk of the nerve. The drawing which I show was exhibited in proof—that, excepting the lateral deviation, there was nothing that the eye could notice. In these cases there is no defect of sensation or loss of taste. The nerve-trunk may be injured by wound, by sloughing abscesses, by the pressure of tumours, or, still more rarely, by disease of the bone through which the nerve passes. Dupuytren has recorded a case, in which a hydatid occupied the anterior condyloid foramen, and Sir James Paget one, in which removal of necrosed bone from the lower and back part of the skull was followed by recovery of the tongue from a much wasted condition.

Mr. Fairlie Clarke has drawn attention to the fact previously mentioned by Dr. Carpenter, that after division of the hyperglossal nerve and paralysis of the muscles on one side, patients can get by education to acquire the power of putting the tongue out straight.

If we attempt a classification of the conditions presented by the tongue, which may rank as symptoms, I think they may be usefully grouped under the following heads:—

1st. As personal peculiarities, having little or no significance in any direction as regards disease. Although unimportant in themselves, these individual peculiarities may stamp remarkable features upon any morbid processes which may supervene.

2nd. We have *the results of former disease.* These are usually the consequences of some bygone attack of inflammation: it may be of a long past attack, or it may be of repeated recurrences. They, like the former, often indicate little or nothing as regards the existing state of the patient's health. They are retrospective symptoms, and, excepting that they may give proclivity to further changes, they help us but little either as regards prognosis or recognition of present states.

The 3rd group will consist of conditions which imply existing disease in the organ itself. It is necessary to carefully avoid mistaking these for conditions belonging to the 4th and last group, in which I place *symptoms produced in the tongue by disease existing in other parts, or by constitutional affections.*

This is a large group, but probably not nearly so large as it was believed to be by our forefathers, and as it is still held to be by many. A great many conditions which have been assumed to be symptomatic of disease in the stomach, liver, or other viscera, or in the body generally, are properly to be assigned to one or other of the former groups.

Keeping in view the classification which I have just suggested, I would, in conclusion, venture to offer a few suggestions, which may be usefully kept in mind when we endeavour to interpret any symptom displayed by the tongue.

First, we must avoid assuming hastily, that the condition present has any connection with the disorder for which the patient consults us. Many patients have habitually a profuse growth of filiform papillæ and great tendency to the accumulation of fur. In others the papillæ are curiously absent, and the tongue may look bald or rough. In others the furrows may be well marked and the peculiar fern-leaf pattern present, and yet these several conditions may imply nothing whatever as regards the patient's health.

In all conditions of peculiarity it is well to inquire whether the patient has ever at any former time been salivated or suffered from sore mouth. For it may easily be the fact that some attack of stomatitis long past may have left the tongue flabby, indented at its edges, fluted on its surface, or more or less bald.

In cases in which we have satisfied ourselves that the conditions shown are neither personal peculiarities, nor yet the consequences of previous disease we ought next to inquire carefully whether any local conditions are present in the mouth which will explain them, and by no means jump to the conclusion that they denote disorder of the stomach or liver. If the tongue is dry we inquire whether the nostrils are stopped, and if it is sore we must examine the teeth and ascertain whether from sharp broken points, from stopping with amalgam or accumulation of tartar, any possible source of irritation exists.

If we have failed to discover in the mouth any cause for disease on the surface of the tongue, we must still hesitate as to suspicion of visceral or blood disorder, and ask whether it be not possible that some irritant may have been introduced in the way of food. There are many fallacies in this direction.

Lastly, if we feel able to confidently exclude all local causes, and obliged to believe that the state of the tongue is in direct connection with the state of the bodily health, we have still before us the difficult task of deciding as to what the nature of the bond of connection may be.

The state in question may still possibly be in no way symptomatic of other disorder and not in any degree consequent on it, but rather part of the general disease.

Above all we must be on our guard against believing that the state of the tongue is a trustworthy criterion as to that of the mucous membrane of the stomach, and remember that for the most part a furred tongue implies that no food has been eaten and little more, whilst glossitis and gastritis are conditions which are mutually independent and but seldom co-exist.

I am aware that in much that I have just hinted at I am speaking in anticipation of any facts which I have yet produced, and I must ask you to be kind enough to wait till future lectures for the proof of some of my propositions.

◆

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL. (a)

By ALFRED BARING GARROD, M.D.,
F.R.C.P., F.R.S., &c.,
Consulting Physician to King's College Hospital, London.

Lecture III.

At the conclusion of my last lecture I spoke of the effects of saccharine food and of different alcoholic beverages on the uric acid excreting function.

To-day, before proceeding to the more purely therapeutic part of our subject, I must devote a few minutes to the discussion of other classes of food in reference to the same function; and, first, with respect to the influence of a nitrogenised, and especially of an animal diet. Observations are not wanting to show the effects of a pure meat diet on the urine. Those of Lehmann are, perhaps, the most satisfactory; they are so valuable that I must now call your attention to the results.

He first determined the daily excretion of the principal constituents of his urine when on an ordinary mixed diet; he then placed himself on a purely animal diet (chiefly eggs) for twelve days; afterwards, for another twelve days, on a purely vegetable diet; and subsequently, for two days, on a purely non-nitrogenised diet, which consisted of fat, milk, sugar, and starch. You will see the results in the table, in which I have left the original numbers obtained by Lehmann in grammes, as the smaller numbers are easier of comparison with each other than would be the case if the results were reduced to grains:—

(a) The Lumleian Lectures for 1883. Delivered before the Royal College of Physicians of London.

Table exhibiting the Mean Results of Lehmann's Observations on the Effect of different Diets on the Excretion of the Urinary Constituents, expressed in grammes.

—	Total Solids	Urea.	Uric Acid.	Salts and Extractives.
On a mixed diet	67·82	32·498	1·183	12·746
On an animal diet	87·44	53·198	1·478	7·312
On a vegetable diet......	59·24	22·481	1·021	19·168
On non-nitrogenised diet	41·68	15·408	0·735	17·130

The conclusions which particularly interest us at present are that the total solids, as well as the urea, are much increased by animal food, while they are considerably decreased by a vegetable diet, and still more so by one which is non-nitrogenised; whereas the uric acid is not nearly so much affected by the nature of the food, provided that it contains nitrogen. Thus, it is seen that the urea, on an animal diet, was to the uric acid 53·198 : 1·478; on a vegetable diet, 22·481 : 1,021; and on a mixed diet, 32·498 : 1·183. Estimating the amount of uric acid, on a mixed diet, as 1, animal food brought it up to 1·27; a vegetable diet lowered it to 0·863; and a non-nitrogenised diet to 0·63.

Lehmann found that after the use of purely animal food the urine of man closely resembles that of the carnivorous mammals, becoming of a light amber colour, having a strong acid reaction, and containing neither lactic nor hippuric acid.

On the other hand, after a course of vegetable food, the urine becomes of a brownish-red tint, is much less acid, often deposits the earthy phosphates, and always contains alkaline lactates with oxalate of calcium—in fact, the urine closely approaches to that of the herbivorous mammal. It might be added, though Lehmann does not allude to the fact, that, under these circumstances, there is also found hippuric acid in considerable quantities.

As a result of all the experiments made by different observers—both on man and the lower animals—I think we may fairly come to the conclusion that meat, taken in such quantities only as are sufficient to keep up the nutrition of the body, has no tendency to increase the excretion of uric acid; that, when the diet is purely animal, but the quantity small (as is the case with the carnivorous animals when in confinement), the uric acid, far from being large, becomes exceedingly small in amount, more especially when it is compared with the urea. On the other hand, that the taking of a great quantity of meat—an excess compared with the requirements of the system—tends to increase the uric acid, though, even then, not more than in proportion to the urea. Funke states that uric acid is less affected by food than any other ingredient of the urine; it is, however, influenced by the time of taking it—that is, uric acid is thrown out in larger quantities after a meal than during the hours that an individual is fasting.

These different facts can be advantageously applied in practice in the treatment of gravel and calculus. In such cases there is certainly no reason why a proper quantity of animal food should not be taken; and the knowledge of this is important, seeing that many patients have been lowered in health by being kept on insufficient diet, with the idea that, by these means, a lessening of the excretion of uric acid would result.

Fatty and Oleaginous Food.—With regard to the influence of such food on the urinary excretion, the experiments of Dr. Böcker seem to be most trustworthy; and from them it would appear that no influence whatever is exerted on the excretion of water, urea, uric acid, or any other constituent of the urine, by taking from about a quarter of an ounce to three ounces of butter daily.

Causes of Gravel and Calculi.—In the course of our experience, most of us have noticed that there are certain individuals who are prone either to pass a urine thick from urates or containing uric gravel, or to void numerous small calculi; others, again, have no such tendency, and only on rare occasions observe any thickness in their urine. Can we link this condition with any other constitutional peculiarity? I think we can; and that we shall find, on inquiry into the history of those liable to pass gravel and calculi, that they frequently inherit gout. In looking over 1,900 cases of this disease, which I have had extracted from my books, I find it mentioned that, of this number, comparatively few had passed calculi. If, on the other hand, we examine cases of calculus, we shall find that a much greater percentage of these patients are the children or grandchildren of gouty parents.

In the course of my experience, it has frequently occurred to me to see a man suffering from gout, and to find that he has one child who has had attacks of joint-gout; another who is suffering from eczema; and a third who is passing uric gravel or calculi. It is not very uncommon to find articular gout and calculus present in the same person. Sydenham, in his own person, was a good example of this combination; in fact, we may fairly conclude that those who suffer from an abnormal condition of the uric acid function on the inner side of our imaginary partition, mentioned in the first lecture—that is, in the blood or system at large—are also more prone than others to experience the effects of a morbid state of the same function on the outer side, or in the urinary tract; in other words, gouty subjects, or those who inherit that diathesis, are more liable than others to gravel and calculus.

There are, however, many influences which act strongly in determining the morbid action to the urinary tract—influences which will often cause the occurrence of such troubles in those who do not inherit them. We see, for example, that, in England, stone is more common in some counties than in others, and at one time of life more than at another. How can we account for this?

Anything that checks the cutaneous function, such as the cold east winds of spring, felt so acutely in Suffolk and Norfolk, appears to act as an exciting cause, and it is well known that in these counties gravel and calculus are very common. When the action of the skin is checked, there is no increase of urates, but an undue acidity of the urine, which leads to the precipitation of the uric acid. Cold alone is not necessarily a cause, for in Sweden and Norway calculous diseases are very rare. Another cause, which, I believe, leads both to an increase of the excreted uric acid and to its deposition in the urinary organs, is portal congestion. Of the exact pathology of this we are at present ignorant, but, in the prophylactic treatment of gravel and calculus, it is important to look to this point; and much good is produced by the frequent use of remedies which tend to relieve such a condition. Hence the value of Carlsbad waters and salts, and of the numerous saline purgative waters which of late years have been so much employed. It must always be borne in mind that, in this administration in the diluted form, the water itself becomes an important element in their action upon the system.

Effects of Water on Gravel and Calculus.—I have already told you that water plays an important part in the formation of uric gravel and calculus, and this must be at once evident when we observe that, in different animals, uric acid is thrown out in the solid or liquid condition according to the relation existing between the solids and water contained in their urine. From this it follows that the proper exhibition of water in the prophylactic as well as the medicinal treatment of calculous disorders must be a subject of much importance.

Many observations have been made on the effect of increasing and diminishing the quantity of water taken with food or when fasting. In the latter case, especially if the water does not pass off by the intestines, it causes the urine to become pale and copious (the *urina potûs* of old writers); but, at the same time, the action of the skin is augmented. It has been asserted that the amount of uric acid is lessened, but it is doubtful whether this is really the case; but any increase in the quantity of the urine helps to keep this principle in solution, and may thus mask its presence.

When the quantity of water taken with food is increased, it appears that certain of the urinary principles are augmented in amount, owing probably to the increased metabolism of the tissues; but at the same time, it is stated that the uric acid is decreased. Further observations are much required before we can come to any accurate conclusions on this point. That the quantity of water passed by the kidneys in a given time has a great influence upon the physical condition of the urine, is evident. If, for example, a healthy man during one day passes an ordinary quantity of urine, and during a second day, but half the amount, it is probable that, on the latter occasion, the urine will be turbid and thick from the precipitation of urate of sodium, whilst the first day's urine will remain bright and limpid: and yet the daily elimination of uric acid may be the same on both occasions, and it only requires that an equal quantity of water should be added to the concentrated urine to bring it to the same condition as the more limpid specimen. If a patient continues day by day to pass urine so concentrated that it rapidly becomes thick, perhaps even in the bladder itself, a very slight change in the acidity of the fluid will cause uric acid to be set free and crystallisation to take place, and then uric gravel, in the shape of cayenne pepper deposit, is formed.

If these changes only ensue after the urine has been passed, of course, it is of no real consequence,; but if they take place while the urine is still within the urinary organs, then either free acid or some urate may become deposited and form gravel, or increase the size of any calculus already existing within the urinary passages.

The deposition of uric gravel is of very common occurrence in children; and I know, from clinical experience, that this often depends on the deficient amount of water excreted. I could give many instances of this, but one or two will be sufficient.

1. A little boy, about five and a half years of age, was passing, from day to day, urine which either contained uric acid crystals or gave rise to a copious red sediment almost immediately after it was voided; his health was otherwise good. I had the urine of the twenty-four hours carefully collected, and found that it amounted to sixteen fluid ounces, with a specific gravity of 1031. On simply causing the child to take five fluid ounces of water an hour before breakfast, and the same before his late afternoon meal, the quantity of urine was at once brought up to twenty-four fluid ounces, and the specific gravity reduced to 1017, nor could any uric acid be discovered when the fluid had stood for thirty-eight hours from the time when the last portion was passed. In a few days the quantity of urine was increased to thirty-seven fluid ounces, and the specific gravity lowered to 1013.

2. A little girl, about eleven years of age, had the same condition of urine as the last, red gravel being constantly present. The total daily quantity of urine was twenty-four fluid ounces, specific gravity 1026. By the administration of water before two of the meals, the quantity was at once increased to forty-five fluid ounces, with specific gravity 1015, and after a few days to about forty-six fluid ounces, specific gravity 1013, the urine remaining free from any red crystals.

These cases, selected from a large number, are sufficient to illustrate the value of water as a therapeutic agent where there is a tendency to the rapid deposition of uric acid from the urine. In many cases it is only necessary to give simple water, such as is usually supplied for drinking purposes—a fact constantly acted upon by patients suffering from such complaints when they resort to warm mineral springs, such as those of Contrexeville, Vichy, and other places.

The importance of the proper administration of simple water in these cases as a part of the diet is the greater, seeing that the plan of treatment can be pursued for an indefinite period; whereas the duration of a course of mineral waters is necessarily limited to a few weeks. I believe that, as yet, the medical profession have not laid sufficient stress on the proper administration of water in the treatment of gravel and calculous diseases.

Effects of Alkaline Treatment.—In the treatment of uric gravel and calculus, the different alkalies and their salts play a most important part, and it is very desirable that their special actions, as well as their relative values, should be clearly made out: this I now propose to do.

I may at once bring to your recollection the fact that, if we give any fixed alkali in the state of a carbonate, it is absorbed and passes through the kidneys in an unaltered form; that is, a carbonate, when taken by the mouth, appears as such in the urine, and, therefore, necessarily diminishes the acidity of that fluid, sometimes rendering it neutral or even alkaline, according to the quantity administered; so that if we give, at frequent intervals throughout the day, a quantity of the alkali equal to the neutralisation of about thirty grains of oxalic acid—the average acidity of the day's urine—we shall, as a rule, keep that fluid in a neutral state.

In considering the equivalents of the different alkaline metals whose salts are employed in medicine, we find that the neutralising power for acids of the different bases must vary considerably. The most practical method of estimating this power is to measure the different alkaline metals, in the form of their carbonates, against each other, when we find that 74 parts of carbonate of lithium equal 84 parts of carbonate of calcium (chalk or its congeners), 106 parts of carbonate of sodium, and as much as 138 parts of carbonate of potassium. This is an important practical fact, and one that must not be lost sight of in the treatment of calculous diseases.

All of us are probably aware that, if an alkaline citrate is given by the stomach, it is changed, either in the blood or kidneys, into the corresponding carbonate. The same is the case when an acetate or tartrate is administered; in fact, most of the vegetable salts are thus decomposed in the system, carbonates appearing in the urine. The establishment of this point is important, inasmuch as we can, by the use of these valuable salts, introduce into the system, through the mouth, salts which have no alkaline action on the stomach and form often an important part of vegetable food, and can still produce the remote alkaline influence where it is wanted; in short, we can often give even an acid salt, grateful and useful to the stomach, and yet have the very opposite effect induced upon the urine.

I will now draw your attention to the salts of lithia, which were first introduced as remedies by myself as far back as 1859. If we look to the atomic weight of the metal lithium, we find it very low, only 7. The number representing the carbonate of lithium is also small—compared with carbonate of potassium it is as 74 to 138; hence the neutralising power for acids possessed by carbonate of lithium is greater than that of carbonate of potassium in the above proportions. Next, if we look at the table of solubilities of the urates, we see that the acid urate of lithium requires only 220 parts of water at the body temperature to dissolve it, the corresponding potash-salt requiring 500 parts, and the soda-salt as much as 1,130 parts, while the magnesia and lime urates take 1,600 and 2,800 parts respectively; so that, with respect both to neutralising power and solubility the lithia-carbonate has a great advantage over the corresponding salts of potash, soda, magnesia, and lime.

Dr. William Roberts, of Manchester, in his paper on "The Solvent Treatment of Urinary Calculi," came to the conclusion that potash-carbonate dissolves uric acid more rapidly than the soda-salt. This he ascertained by placing sections of uric acid calculi in phials, and causing currents of the different solutions, at blood-heat, to pass over them at a regulated rate. He also found that the strength of the solution employed was of much importance, the greatest amount of solvent power being exhibited in solutions containing from forty to sixty grains of the alkaline carbonate to the imperial pint (twenty fluid ounces). Below this strength, the power of the solutions gradually declined, until, with those which contained less than three grains to the pint, the solvent power scarcely exceeded that of water. On the other hand, if the strength was above sixty grains to the pint, the pieces of the calculus became encrusted with the alkaline bi-urates which were then deposited, and thus the further action of the solution was impeded. This was especially noticeable when the strength of the solutions was much above one hundred grains to the pint.

Lastly, it will be observed that, when the comparison of the solvent power was made between the potash and lithia salts, using twenty and afterwards ten grains to the pint—the quantity used by Dr. Roberts in his lithia experiments—the results were in each case more than 50 per cent. in favour of the carbonate of lithium.

It will thus be seen that so far as soda and potash are concerned the results obtained exactly agree with those of Dr. Roberts; they exemplify the greater solvent power of the latter over the former, a result which might have been clearly anticipated, but, on the other hand, they are totally opposed to his conclusions with respect to lithia. How is this to be explained?

Dr. Roberts uses the expression "only weak solutions of carbonate of lithia *could* be employed," italicising the word "could;" and he appears to have used in his four experiments, two of which are given in the Medico-Chirurgical Society's "Transactions," solutions of the strength of 10 and 20 grains to the 20 ounces, whereas, in case of the potash, he found that a 60-grain solution is the most powerful. Now it will be seen in the table that solutions of carbonate of lithium were employed containing 60 and even as much as 100 grains to the imperial pint, and that, in the case of lithia, as the strength was increased the solvent power also was augmented. I should imagine that Dr. Roberts either used an impure carbonate of lithium or assumed that only one grain was soluble in the fluid ounce, as he used only 10 and 20 grain solutions; whereas as much as 100 grains can be dissolved, at the temperature of the body, in the imperial pint of water. Impurity of the salt and the use of solutions which were far too weak will at once explain the discrepancies and the cause of the erroneous statements with regard to the solvent power of the lithia salts. No one who has thoroughly investigated the action of these salts, in comparison with those of soda and potash, as internal remedies, can come to any other conclusion than this, viz., that lithia-salts are far more powerful solvents of uric acid than potash-salts, while these latter are more efficacious than those of soda.

We have only to take three small phials filled with a solution of the three carbonates of the same strength, and to put into each the same quantity of small uric calculi, the amount being such that the lithia will dissolve them. If we carry these in a warm pocket, after a short time it will be seen that all the calculi have disappeared from the lithia solution, while more than half are left undissolved by the potash, and about four-fifths by the soda solution.

I have been informed by some patients that they have been deterred from using lithia-salts, although they had found them valuable, by having been told that their employment would prove injurious, owing to their caustic effects upon the renal organs. In answer to this objection, I may say that I have found the action of carbonate of lithium to possess less destructive power than the corresponding salts of potash and soda upon animal tissues.

The only effect that I have ever noticed has been that, when the quantity is increased beyond a certain amount, a little tremor of the hands is produced, which passes off at once on the diminution or omission of the dose of the salt. I have known patients of their own accord continue the use of lithia-salts for more than ten years, with the effect of entirely preventing the recurrence of the symptoms to remove which they were first prescribed, and without the production of any injurious effect. For myself, I have not the least doubt as to the value of lithia-salts as therapeutic agents, and am convinced that, by their employment, depositions of uric acid in the renal organs can to a large extent be prevented. Free dilution and administration on a fasting stomach are points of much importance, which should be attended to in the administration of alkaline remedies. I have been much in the habit of using potash with lithia, in the form of the citrate or the carbonate, the former to give neutralising, the latter to increase the solvent power.

In concluding my remarks on the action of alkalies, I may state that I do not myself believe in the value of any injections into the bladder in the treatment of vesical calculus; at the very best, the process must be most tedious; and at the present day, when the surgery of the subject has reached to such great perfection, when a calculus can often be removed completely from the bladder in a few minutes without the use of the knife, I cannot but think that the surgeon is better qualified for the treatment of such cases than the physician.

(*To be continued.*)

IS CONSUMPTION CONTAGIOUS?

By BERNARD KELLY, M.D.,
Medical Officer for the Fifth District of St. Olave's Union, Southwark.

Now that the Collective Investigation Record is soon to appear, it will be interesting, and, I have no doubt most instructive, to read the report on the communicability of phthisis. Notwithstanding the modern craze respecting the *rôle* supposed to be enacted by the all-potent and ubiquitous micro-organisms in this, and many other diseases, and without, at all, the least pretension to the art of prophecy, I am strongly disposed to believe that the great weight of medical opinion will lean to its non-contagiousness. However, time will show. To the inquiry paper sent out by the committee at the commencement of last March, I gave the following reply:—"No; nor do I believe in its contagiousness or infectiousness, at least in the strict etymological sense of the terms. That it is communicable, however, I can well understand, just as we know hysteria, for instance, is communicable to susceptible persons by the sheer force of example. Here there is no question of the existence of bacilli or bacteria, of contagion or infection. A man, for instance, contracts or inherits phthisis. He is constantly attended by a faithful and devoted wife, who notes every symptom, and who fluctuates between hope and fear with the daily exacerbations and remissions of the disease. She not unfrequently occupies the same bed, and is thus exposed to the baleful influences of the variations of temperature due to the cold, the hot, and the sweating stages. In this way a *hexis*, or habit is artificially produced, and what begins as a habit may well terminate in confirmed consumption. For this reason, I always interdict when practicable, husband and wife, either being the victim of phthisis, occupying the same couch, or even the same chamber. But I fear I am digressing."

It flatters not a little one's *amour propre* to find that his views on any subject are entertained by men occupying prominent positions in their professions, and whose opinions and judgments are consequently authoritative; and that too, without the suspicion or possibility of a secret understanding between them. Thus, Dr. J. Solis Cohen says: "I am strongly impressed with the opinion that phthisis can be contracted, that is to say, is communicable (rather than contagious, in its strict sense), from frequent continuous contact with the phthisical." Professor Herbert Clapp, of Boston, Massachusets, arrives, on the subject, at the following conclusions:—"1. No person, particularly if young, should be allowed to sleep in the same bed, or even in the same room with a consumptive. 2. No person should be allowed to remain for too long a time in too close or too constant attendance on a consumptive. 3. Ventilation as perfect as possible should be secured." Respecting the first and second injunctions, resembling as they do, so closely the maxims I have enunciated in my reply, no comments are required at my hands. As regards the third and last, I must make an exception, there seems such a strange confusion and misconception as to what "perfect ventilation" really means. With some, ventilation would not be considered perfect unless the windows and doors of a house be open during the entire day, and bed-room windows during the night, winter and summer, and all this quite irrespective of the physical condition or state of bodily health of the occupants. He would indeed be a bold man who would carry out all this in practice, but, even if he did so with impunity, it would scarcely be safe to make the rule absolute and applicable to all mankind. That there are rough, robust natures who can bear the vicissitudes of climate and temperature with all the serenity and indifference of savage tribes I can well imagine, but for one such individual there are thousands —nay, even millions—for whom such an ordeal would be inevitably fatal. Indeed, for the consumptive so far as I have observed, the reverse of this is most beneficial, an equable climate—one approaching the natural temperature of the body in health—being the least dangerous, and most agreeable to the patient. *In medio tutissimus ibis* is a rule as safe to follow here as in steering a ship between Scylla and Charybdis. We should never forget that the phthisical is one who can seldom safely take active exercise to develop caloric as required, and is therefore easily depressed by the action of cold. During the hot, burning stage of hectic a low temperature is indicated, and is highly serviceable, as cutting short its duration, and thus saving the system from the wasting of rapid metabolism, or destructive metamorphosis of tissue.

Again, with respect to the purity of the air as a preventive or curative agent there are some curious facts which appeal to our judgments in rather a circuitous but yet cogent way, and which would seem to militate against many of our preconceived notions, and make us reverse much of what we have hitherto enforced in practice. Rokitansky and, more recently, Dr. Addison, have held the view that an excess of fibrine (hyperinosis) in the system predisposed to, if not favoured, the development of tubercle. In pregnant women the disease, if already present, is held in abeyance during the period of gestation owing to the fact that the arterial blood assumes, in a large measure, the venous character, from the excess of carbonic acid in the system in general, but in the circulating fluid in particular; and as venous blood contains a less proportion of fibrin (hypinosis) than does the arterial, the arrest, or prevention, of the development of phthisis in the gravid state is thus rationally and physiologically explained. The bright carnation or vermillion hue of the skin of consumptive patients furnishes additional proof of the excess of oxygen over carbonic acid in such cases, and would seem to indicate the most rational remedy for the prophylaxis or cure of the disease, which, under the circumstances, would necessarily be the very opposite of that recommended by so many writers and authorities on consumption. The solvent action of venous blood on fibrin prevents materially the deposition and development of tubercle, and goes far to strengthen the significance of the foregoing views, so that we are forced to infer that air contaminated to a certain extent by carbonic acid is not, after all, so deleterious to phthisical patients as we have been led to suppose.

The well-known anæsthetic action of carbonic acid upon the terminal branches of the sensory nerves in general may not only allay "formative irritability," which, according to Virchow, plays such an important part in the genesis of tubercle and other morbid growths of tubercle, but also effectually calm the incessant, hacking cough which accompanies phthisis in all its stages, and thus become a potent preventive, as well as a curative agent, in the disease.

Rotherhithe, June, 1883.

A PRIVATE telegram from India mentions that Dr. Charles Little, of the Indian Medical Service, Sanitary Inspector of Berar, has been killed by a tiger.

Clinical Records.

MIDDLESEX HOSPITAL.

Cancer of the Male Breast.

Under the care of Mr. HENRY MORRIS.

[For the report of this case we are indebted to Mr. W. Roger Williams, F.R.C.S., Surgical Registrar.]

This patient, a widower, æt. 64, was admitted into the Middlesex Hospital on Feb. 9th, 1883, under the care of Mr. Henry Morris. He was a sallow, but well-nourished, man; a joiner by trade. His hair, formerly dark, had grown grey, but there was no arcus senilis; and his general health was fairly good. His right breast was the seat of a hard, knobby lump, about the size of half an orange, adherent to the skin over it and to the subjacent parts. The nipple and areola had been completely destroyed by cancerous ulceration; and there was now in this situation an oval ulcer, 2¼ by 1¼ inches. The right axilla was occupied by a large mass of diseased glands; and there were some smaller ones similarly affected just above the right clavicle. There were no signs of secondary disease elsewhere. The integument, especially about the neck, presented many small warty, fibroid, and varicoid outgrowths. A year and a-half ago, he said, he first noticed a hard swelling, about the size of a marble, in his right mamma. He had experienced no previous injury or disease of this part, and he knew of no cause for it. He had previously enjoyed very good health, with the exception that fourteen years ago he had a severe attack of general eczema, from which he continued to suffer, more or less, until the outbreak of the present disease, when it got quite well, and has remained so since. There was no history of cancer, tumour, or phthisis in the family.

On Feb. 17th Mr. Morris excised the diseased mass and a portion of the pectoral muscle to which it adhered. The axilla was freely opened up, and several diseased glands were removed from it; but the whole of them could not be extirpated, on account of their contiguity to the great vessels and the apex of the axilla. The wound was dressed with terebene oil and absorbent cotton-wool. On *microscopical examination* the growth proved to be an example of the acinous form of carcinoma, having a well-marked but not very abundant fibrous alveolar stroma.

He progressed fairly well until the seventh day after the operation, when the upper limb became much swollen, and the morning temperature went up to 102° F. Erysipelas of the wound declared itself a few days later, followed by pulmonary complications and an asthenic type of fever, of which he died on March 7th—the nineteenth day after the operation.

At the *necropsy* by Dr. Fowler on the following day the right upper limb was found to be swollen and œdematous. A ligature had been placed round the subscapular vein, and from this thrombosis had spread upwards to the axillary vein, which was completely blocked by firm clots. Thence the thrombosis had extended along the vessel upwards to the clavicle and downwards to the forearm. High up in the axilla and beneath the pectoralis minor several cancerous nodules were found. Both pleuræ were lined throughout their whole extent with a thick, fibrinous membrane of recent formation. The left pleural sac contained 14 oz., and the right 4 oz., of flaky, puriform fluid. The lower lobes of both lungs were partially collapsed from the pressure. The upper lobes were emphysematous and congested; the lower, non-crepitant and œdematous. The left ventricle of the heart was hypertrophied. The liver was large and fatty; its weight, 14 oz. Both kidneys were rather small; their secreting structure was somewhat wasted, and presented a few small cysts. There was an excess of fat in the hilus of each organ. No secondary deposits were found. There were no other noteworthy changes.

Remarks.—Cancer of the male breast is a very rare affection. Walshe found (*vide* "Nature and Treatment of Cancer," 1846, p. 467) that the Paris registers for ten years supplied 1,147 deaths from cancer of the breast among the female population, and only five among males—the liability of the former being, therefore, about 230 times that of the latter. Sir James Paget, however, in his "Lectures on Surgical Pathology" (vol. ii., p. 324), gives

2 per cent. as about the proportion of cases of scirrhus of the breast that are males. I think this latter estimate greatly exaggerates their frequency. Out of 297 cases of cancer of the breast admitted into the Middlesex Hospital during the last eight years there has not been another example of this kind.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

AT the closing meeting of the Surgical Section, in the Albert Hall, Royal College of Surgeons, Mr. J. K. BARTON, President, occupied the chair.

Mr. WM. STOKES, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

Living specimens and specimens by card were exhibited by the President, Mr. Croly, Dr. Baxter, Mr. Thomson, Mr. Wheeler, Dr. Mapother, Mr. Stokes, Mr. Coppinger, and Dr. M'Cullagh.

The PRESIDENT read a paper on

EXCISION OF THE HIP.

He pointed out that surgeons are much divided in opinion as to the benefits derived from this operation—some, seeing the results so often unfortunate, holding that amputation of the hip is in extreme cases better that excision; others, including those who have had most experience of the operation, clinging to the belief that in excision we possess the means of saving those cases of hip disease which will not yield to expectant treatment. In two cases he obtained an encouraging amount of success, a year having elapsed since the first operation, and six months since the second, viz.:—Case I.: L. M., æt. 14, a delicate, strumous girl, with sinuses round the diseased hip, from which there was copious suppuration, was evidently sinking from the effects of the disease when the operation was performed, in May, 1882. A marked improvement in her general condition followed the operation. She was able to leave hospital in three months for the country, where she has remained since. She is able to walk with crutches, but there are still open sinuses, evidence of the existence of carious bone; but the union between the cut end of the femur and the acetabulum is firm, and capable of bearing the patient's weight without pain.—Case II.: M. R., a healthy-looking girl, æt. 12, the subject of recurrent disease in the trochanter major. The hip was anchylosed when she was seven years old, in the semi-flexed position. Disease had lately been set up in the trochanter by a fall. The operation was undertaken to remove the progressive caries of the trochanter, and to rectify the anchylosis, which rendered her a cripple. It was performed in October, 1882, and has been successful in accomplishing both objects, as the girl is now able to walk, and the limb is straight, though four inches shorter than the other. The author insisted on the importance, in the after-treatment of these cases, of maintaining a free drain from the wound, submitting that the accomplishment of this must be the first care of the surgeon.

Dr. R. M'DONNELL said his own experience of excision of the hip-joint was not altogether favourable. At the same time, the operation should not be set aside; he believed it was legitimate in suitable cases.

Mr. STOKES remarked that in the Richmond Hospital their experience of excision of the hip-joint had neither been very great nor very favourable. In one case in which he had performed the operation, the result was the reverse of satisfactory; but it was in every respect an unfavourable case. Had he had his own will at the time, he should, on performing the excision and finding the large amount of disease that was present, have proceeded to amputate the hip-joint, but he was precluded by the express directions of the patient. He mentioned this to show how difficult it was beforehand to form a just estimate of the amount of disease that might be present. In dealing with caries of other articulations this was not altogether the case. He asked the President's opinion with regard to Thomas's splint, which he used in one of the cases. Having tested the splint himself, according to the inventor's directions, in the case alluded to, he was obliged, after a few days, to remove it, owing to the great pain caused by the pressure of the splint against the spine. He substituted Liston's long splint with a weight attached. The President being a warm advocate of antiseptic treatment, Mr. Stokes asked why he abandoned it in favour of the so-called open treatment of wounds.

Mr. BENNETT said the same question struck him as that which Mr. Stokes had just asked, and the answer might be anticipated, that the conditions under which the President operated were not those in which the Listerian treatment could be adopted, being cases in which there was already an open suppurating wound existing for some time. But a more important question than the immediate detail of treatment was one on which he desired explanation. The difficulty in those cases was to determine the conditions under which the operation was likely to succeed. He heard it laid down in the debate at the International Medical Congress that as a rule the operation should not be undertaken, except under conditions where the alternative was amputation of the hip. He thought amputation should take precedence. He asked the President, however, what he regarded as indications for the operation—whether it was a mere alternative to amputation of the hip, or whether it should be adopted under such grave conditions.

Mr. CORLEY, referring to the question of age in determining the operation, mentioned the case of a patient, æt. 36, in whom all the conditions for a favourable result existed— a limited amount of bone disease, while the operation itself was not attended with considerable difficulties. It was impossible, however, to secure anything like immobility. He did not use the wire apparatus recommended in Sayre's work, but put up the patient in Bryant's double splint, and endeavoured to carry out antiseptic treatment. The difficulty was great, as a large abscess surrounded the joint. But the unfortunate result depended on the complete impossibility of securing anything like rest to the fragments in position. Modern success depended more on securing perfect immobility than on antiseptics, and until some means were had to secure this desideratum, the operation must be looked on as a serious one.

Mr. WHEELER asked what was the condition of the acetabulum? His own experience in five cases of the operation was that it was favourable to life. In three, the results were very favourable; but two still had sinuses. The splint he used was Bryant's, with a posterior splint running up behind on the nates. The treatment he adopted was open dressing with plenty of drainage. He believed in antiseptic treatment, but not in Listerism. With the observation of Mr. Stokes' that it was more difficult to determine the amount of disease in the hip-joint than in any other he disagreed. In the knee it was equally difficult. It was a great point that the sinus did not open posteriorly. In those cases that turned out well he made an opening below, and drew the drainage tube through, to be able to syringe from the top and prevent any collection of matter.

Mr. THOMSON said the discussion showed that the experience of surgeons in and out of Dublin was very disastrous in connection with the operation of excision of the hip. Even Mr. Barton, who had the largest experience of the operation of any surgeon in this country, had only been able to bring forward one case out of nine that he would claim as a success, and in that case the patient was unable to progress without the aid of crutches, and unable to bear the weight of the body. He had done the operation himself in one case which he was looking after for Mr. Stokes during his illness, and in that case, after a long period of illness, the patient gradually sank and died. He thought the great practical point to be decided in the discussion was the proper time at which the operation should be commenced, if it was to be undertaken at all. There was no doubt the operation of excision of the hip-joint was very little more fatal than leaving those cases alone, that is, as regards those that had a fatal result. A considerable proportion recovered. In the *Medical Press* he saw that the percentage of fatal cases that were not treated at all was something like 40, while the fatal results from excision numbered something more. So that practically there was very little difference between interfering by excision and leaving the patient alone. He had an opportunity of seeing a case treated by the Listerian method in St. Thomas's Hospital, London. An abscess had formed, and the disease was very rapid in its progress. The case came under the care of Sir William MacCormac, who at once determined to excise, and cutting down upon the part, he found the bone was diseased, but that the disease had not proceeded to such an extent as was usually the case before the operation was undertaken. In that case the wound remained perfectly aseptic throughout. The patient had been operated on six weeks before he saw the case. The wound was perfectly healed at the time, while the patient was able to get out of bed and stand on both limbs without the aid of a crutch. That was a point which went to prove two things—the great importance of early operation in those cases, if there was to be any hope of sinuses at all, and the great advantage which must always follow the adoption of the true Listerian method.

The **PRESIDENT** replied. He agreed with Mr. Stokes's experience that Thomas's splint was singularly unsuited for cases of excision, the pressure of the rigid bar down the back of the hip not being at all comfortable. In the cases in which he used it he had to lay it aside. Thomas's splint was, however, useful for recovering hip disease, where the patient would be allowed to move about. Replying to Mr. Stokes's question, he adopted the open treatment, having first tried various other methods, including the Listerian; but he did not find it to answer well. Indeed, the conditions were such as should have enabled him beforehand to say it would not answer well. Why? Because the excisions were only partial ones, unlike the excision of joints where all the diseased portions were removed, as in the elbow or knee, and where the healthy cut parts could be closed against one another. But where there was partial resection the result was bone remaining in a partly diseased state behind and the soft part in a very unhealthy state. Thus, there was a large cavity through which there must be the products of inflammatory action discharged. His experience fortified him in saying what all would agree was reasonable in theory, that the free exit of drainage from the wound was the first thing to be gained. He, therefore, thought the open treatment necessary to gain that desideratum. Having reported one of these cases some years ago, it was remarked on that occasion that the constant syringing with antiseptic solution—chloride of lime, carbolic acid, &c.—the constant washing away of the discharge, was in itself antiseptic treatment. While the method of closing wounds in which the flesh might unite by primary union was inapplicable here, yet the great principle of removing putrefactive material remained the same, though carried out in another way. Therefore, he was not casting the slightest slur on the antiseptic method, but adopting the suitable way of applying it to cases of partial excision, It appeared from the discussion that they ought to aim at osseous union in excision of the hip. That was not his experience. They should simply aim at fibrous union as supplying, in successful cases, all the results they could possibly wish—complete firmness with mobility. For this purpose it was not so necessary that absolute rest of the parts should be maintained, and the apparatus he applied had to be laid aside, and he fell back on the simplest possible method of keeping the limb straight. Sir William MacCormac's case was an exceptional one; but ordinary cases of a strumous type commencing in the trochanter towards the head, involving the joint in the secondary degree, were not suitable for excision in a very early stage, for the simple reason that a great number of them would recover by expectant or ordinary treatment. Therefore, the surgeon must wait until the abscess had formed, or the disease had entered into what was called the secondary stage. In this case the question might arise whether amputation or excision ought to be preferred. Amputation at the hip-joint was open to this objection—that it was a greater shock to the patient than the operation of excision. No doubt it was difficult to say how far the disease had progressed, but he would not perform that operation when he could by any reasonable section of it gain recovery, and a tolerably useful limb. It was better for a child to have one limb some inches shorter than the other and useful, rather than have none at all and cut off at the hip-joint. Mr. Corley had asked what age was favourable? He agreed with Mr. Corley, that, as age advanced the risk increased; but his own cases were all of young children. Replying to Mr. Wheeler's inquiry as to the condition of the acetabulum, in most cases he said it was not very bad—there was no necrosis of the bone. The cartilage was destroyed, but the bone itself—or the ilium—was not extensively diseased. He looked on the femur as more of a difficulty than the acetabulum. Mr. Thompson had taken a gloomier view of the results of excision than was compulsory, for damaging as the results had been, they were not so gloomy as he had pictured. The young man, for instance, was able to hop on the diseased limb, bend it, abduct it, flex it, and rotate it. That was a rarely successful case. The second was also successful, as there was fibrous union established. The time for operation must be when the case had passed recovery from expectant treatment, and before degenerate changes had begun. As pointed out by the Clinical Society of London, the percentage of recoveries was considerably above that of recoveries without operation.

Dr. **THEODORE STACK** read a paper on

THE REPLANTATION AND TRANSPLANTATION OF TEETH.

This subject, he stated, was first worthily introduced into surgical literature by John Hunter, in whose museum there is to be seen an immature canine transplantation into the comb of a cock with perfect success. Having fallen into disuse soon after Hunter's time, this method of treatment received a fresh stimulus from the practice, at St. Bartholomew's, of Mr. Coleman; and, more recently, Professor Magitot, of Paris, had made a valuable communication on the subject to the International Medical Congress. Replantation may be found a useful therapeutic measure in, firstly, pulp exposed, or nearly exposed, with carious cavity extending under the gum; secondly, external violence knocking the teeth out; thirdly, accidental extraction; fourthly, obscure cases of neuralgia referred to sound teeth; fifthly, alveolar abscess complicated or uncomplicated. It will be undertaken most frequently in cases of alveolar abscess. The primary cause of alveolar abscess is in nearly every case a petrifying pulp. A secondary cause may be a small portion of the tip of the root becoming necrosed by the abscess after it has lasted a little while, dissecting off from the part the periodontal membrane. Magitot proposed extraction of the tooth, resection of any necrosed part, and replantation, and claimed a success of 92 per cent. Mr. Finlay Thompson proposed, after resection, to cap the end of the root with gold, and to introduce a gold tube into the root for drainage. This method seems equally elaborate and useless. Mr. Coleman proposed to fill the root antiseptically. This method appeared to fulfil the indications most fully, and some of Mr. Coleman's failures must be attributed to his dipping the tooth in too strong carbolic acid before replacement. Out of a table of some thirty cases made out by Mr. A. W. W. Baker, and Dr. Stack from their private and hospital practice—all of which were successful—a large number had been treated by resection of the root, filling the root with creosote and iodoform, and free incision into the alveolar abscess. Referring to the liability of these teeth to absorption—a danger mentioned by Tomes, Coleman, Nilhod, and others—Dr. Stack stated he believed this danger only applied to teeth which had been so treated when out of the mouth as to cause death of the periodontal membrane, either by too long delay, or by the use of some too strong chemical agent. It was not due to rending of the alveolar connections, for admittedly, teeth violently knocked out and quickly replanted, nearly always succeeded. Nor was it due to placing foreign material in the pulp chambers and canals, for Dr. Stack was proud to say that, in cases of teeth pivoted by two of their oldest dental surgeons—Mr. Robert Moore and Mr. Daniel Corbett—it was no uncommon occurrence for the roots to last twenty or thirty years. In the museum of the Dental Hospital of Ireland there was a specimen of a pivot tooth, presented by Mr. Corbett, which had lasted thirty-seven years. In the allied operation of transplantation when the scion tooth was always perfect, it is still undecided whether the pulp should be exterminated or not. Mr. A. W. Baker, Mr. Abraham, and Dr. Stack were, he believed, the first who had established by actual microscopical examination in the human subject, that the pulp chamber in the scion tooth could, after replantation, again enclose living contents. This was a possible, perhaps a probable result, but by no means a universal one. Dr. Stack believed that the operation of transplantation was likely to grow in favour, especially in hospital practice, where the patients were unable to pay for good artificial dentures. Dr. Stack said he was much indebted to Mr. Abraham and Dr. Richard Hayes for the assistance they had given himself and Mr. Arthur Baker.

Mr. **ABRAHAM** read a short treatise on the subject.

Dr. R. **MCDONNELL** said the paper was one of extraordinary interest, not only to the dental surgeon, but also to the surgeon occupied in the careful study of the processes engaged in the absorption of bone and diseased tissues. Savory, referring to Gulliver's paper on the absorption of bone, had asked, was dead bone absorbed? He came to the cônclusion that, according to Gulliver's experiment if dead bone was lying in the midst of surrounding tissues, it was not absorbed. But his experiments extended only for a short time, while absorption was a very slow process of years. Pressure was of importance; for instance, when allowed to make experiments in this country, an ivory peg put loosely through a bone and taken out after a few weeks was just as smooth as whem hammered in, but when taken out, after being there for months, it was deeply eroded, and it was evident that some process was going on. Others pointed ont that bone, when engaged with a foreign body, was able to regenerate new bone, or attach structures that came in the neighbourhood of it, and he demonstrated the rapid development of new bone by transplantation into the bone of a chicken. From the cases in question, however, he (Dr. McDonnell) would be most cautious in drawing the conclusion that it was revived pulp. It might be that granulations had sprung up and filled the cavity, that the tooth was acting like a sponge graft, and therefore would be in the happy position of bearing a pulp without any nerve in it. He did not think any one who had heard the paper could scout the idea of antiseptics.

Mr. **Wheeler** said he had brought forward a paper in which he had strongly advocated antiseptics, laying down, however, the difference between antiseptic surgery and Listerism. Anything that fell short of the gauze and the spray as MacCormack had stated was not Listerism; but he believed in drainage, in rest, in cleanliness, what they all aimed at. As to ivory pegs being absorbed, he had seen them five or six times pegged into the tibia. Holes were bored and the pegs put into the wood, in the first instance, to make sure they would not get small. It was not the experience of many surgeons that ivory pegs were absorbed.

CLOSING REMARKS.

The President, in closing the meeting, thought they might congratulate themselves on the work of the past session. The papers read showed an amount of preparation that was in the highest degree encouraging, while the remarks made in discussing those papers evidence knowledge and depth of thought that equally augured well for the future. A suggestion made in the Council might perhaps be carried out next session—to group subjects so as to have two or three papers on the same subject read at the same meeting, and let these be discussed together. That course had been found to work well elsewhere, and to add very much to the interest of the meeting. The living specimens exhibited during the session had proved a most successful feature. To the General and Sectional Secretaries thanks were due for their admirable arrangements.

THE HOSPITAL MANAGEMENT CONFERENCE.

There was held in the hall of the Society of Arts, last week, a most important meeting, convened under the auspices of the Social Science Association with the object of discussing the question of hospital administration, and for the consideration of proposals made with a view to averting the periodical crises experienced on the part of many of our more important charitable institutions. The conference was opened on Tuesday, under the presidency of Sir T. Fowell Buxton, who sketched the history of the subject under review for the past ten years, and to which especial prominence had been given owing to the serious financial difficulties into which not a few great hospitals had fallen. In the opinion of the chairman, and that also of nearly all who took part in the conference, the appointment of a Royal Commission on hospital administration is essentially required at the present time; and the adoption of measures with a view to obtaining such assistance was urged by a majority of speakers. That stimulus will be given to efforts in this direction as a result of the deliberation there can be little doubt; nor either that the problem how to relieve the pressing needs of insolvent institutions will be worked out on lines that have been more or less completely sketched in recent newspaper articles, and in the papers read before the conference.

The first topic discussed was that of constitution of managing committees, on which subject a paper was read by Mr. Burford Rawlings, who advocated the election of *bonâ fide* working committees, including members specially chosen to discharge particular duties for which each should be specially fitted. Thus, he would include on the committee a medical member, a legal member, a member with actual executive experience, *e.g.*, an ex-house-governor or ex-treasurer, and two or three business men with a strong liking for real work. Dr. J. S. Bristowe supplemented Mr. Rawlings' paper by a detailed account of the constitution and mode of working of the house committee of St. Thomas's Hospital, which, as recently framed, included the treasurer, almoners, and six governors, of whom two are past physicians or surgeons to the hospital. Experience had shown, said Dr. Bristowe, that such a committee worked harmoniously together for the advantage of the charity, and of those who came to it for treatment; he did not, however, think it advisable that all members of the staff should be admitted on the house committee, nor that medical members of the committee should be entitled to vote. While, however, approving generally of the committee as constituted at St. Thomas's, he thought the medical representatives should be annually elected by their own colleagues, and not, as at present, by the treasurer. This change, moreover, he believed would ere long be made.

A discussion ensued on these two papers, in which a number of gentlemen representing provincial hospitals engaged; and the general tone of the remarks made indicated a feeling in favour of medical representation on the managing committee. In several instances such representation was said to have existénce; and always, wherever it had been introduced, the results had proved eminently satisfactory. It is not, of course, to be expected that a perfect system can be at once devised, as was pointed out by Mr. Bousfield, a member of King's College Hospital committee; but with the expressions of opinion already obtained, it ought not to be a difficult matter to suggest some arrangement which, while avoiding the errors of the past, shall at any rate include the beneficial feature already successfully introduced in those places where, as at St. Thomas's and King's College Hospitals, at the Western Infirmary, Glasgow, at the Nottingham General Hospital, and elsewhere, a definite position is given to the medical staff in matters relating to government of the respective institutions.

The second subject entered on is perhaps the most important of any that have arisen of late years in connection with charitable relief, that, namely, of payments by patients. Mr. Timothy Holmes attacked the problem, "Can the system of free and paying beds, and of payment by out-patients be successfully applied to existing hospitals?" While approving the introduction of a system of treating in-patients on the payment system, he saw no reason for urging its extension to out-patients, wherein he was at issue with the reader of the second paper, Mr. J. S. Wood, Secretary of the Chelsea Hospital for Women, and of the Bolingbroke Pay Hospital. This gentleman strongly insisted on the good results accruing from adoption of the contributing system, and instanced the great advantage gained from it at seven general and twenty-eight special hospitals. Dr. Fairlie Clarke, on the same subject, recommended careful classification of applicants for free treatment at hospitals, and advised that those only who were absolutely unable to pay for assistance should be treated gratuitously. A practical and thoroughly sensible suggestion was also made by the same authority to convert free into provident dispensaries, whose officers should be remunerated in proportion to the number of cases treated. Against the provident dispensary plan, which found support also in a paper by Mr. A. G. Henriques, it was urged by Lord Cork that their multiplication would starve the general hospitals by diverting subscriptions which would but for them be handed over to the great charities. This argument, however, was based on the assumption that such provident institutions could not be self-supporting, and on the evidence of Mr. James Cropper, M.P., this was not a wholly justifiable conclusion, several provincial self-supporting dispensaries being now in existence. There was forthcoming also from other speakers abundant testimony in proof of the willingness of patients, when called upon, to respond to the demand for contributions towards their support in hospital. It is not surprising, therefore, to find that a tendency was shown at the conference to limit out-patient attendance at general hospitals by means of provident dispensaries, some, notably Dr. Acland, even recommending direct union of the two classes of institutions; and we may not improperly anticipate a material and salutary change in this direction in the not very distant future.

On the resumption of the Conference on Wednesday, the chair was taken by Mr. F. S. Powell, the first subject of discussion being "The Financial Difficulties of Metropolitan Hospitals," introduced by Mr. H. C. Burdett. The author of this paper advised extraordinary efforts to raise the regular income of hospitals, and the removal of certain of them from their present sites to situations where they would be of greater service to larger numbers of poor. Mr. Burdett concluded by insisting on the necessity for a Royal Commission of inquiry. After some discussion on and criticism of the statements contained in the paper, Mr. Thomas Blair, general manager of the Leeds General Infirmary, read an essay on "The Differences between the Systems of Raising Income and Controlling Expenditure at the Metropolitan and Provincial General and Special Hospitals." Such differences, it was shown, were found in the reliance placed on spasmodic efforts in London, whereas in the provinces systematic use was made of facilities for raising money through benefit entertainments, voluntary subscriptions, and organised collections. In a paper on the same subject by Mr. R. Hordley, secretary of the North Staffordshire Infirmary, monthly detailed statements of the cost per head per day of patients in hospitals was recommended as a means of checking unnecessary expenditure.

In the discussion which ensued various remedies to meet the existing losses were proposed—such as careful and frequent scrutiny of expenditure, with a view to its due control; the exaction of money payments from patients; reduction of drug bills; and rejection of those who could not rightly urge the plea *ad misericordiam.* The result of the deliberations, while not perhaps adding anything essentially novel to what has already been uttered in this connection, has at any rate served to emphasise the main conclusion adopted—that there is dire need of some mode of coping with the increasing contrast between income and expenditure in many of our hospitals. If it does no more than clear the ground for further practical consideration of this vital question in economics, the Conference will have produced some valuable consequences.

The remainder of the sitting was taken up with discussion of the relation of convalescent institutions to hospitals, and the question of the appointment of a Royal Commission of inquiry; and the general result of the Conference was admirably expressed in the concluding speech of the chairman, who said it had been a great satisfaction to him to find an almost universal consensus of opinion adverse to the management of hospitals by guinea governors, and he hoped the time would soon come when the monstrous absurdity of management of charities by voters would cease to exist. It was necessary that the medical staff should either have a seat on all the boards, or an absolute right to express their views before the boards. With regard to their finances, the contrast between the active energy and liberality of the working men in the North, and the miserable apathy and dependence of those in London, was no credit to the metropolis. With respect to paying patients, he never could see why sick and benefit clubs should not in some way or other be intimately associated with the local hospitals. Medical schools were great national institutions, as important to the nation as the universities. No doubt they created some inconvenience, but the presence of students was a great advantage to a hospital. He congratulated the Conference on the entire absence of ill-feeling; not one word of objection had been uttered to the appointment of a Royal Commission even by those who were on the councils of hospitals, and he therefore thought it must be taken for granted that the managing bodies were no longer averse to such a commission.

◆

DR. FREDERICK WILLIAM WARREN has been appointed to the Surgeoncy of the Adelaide Hospital, Dublin, vacated by the death of the late Dr. Richardson. Dr. Warren is a Bachelor of Arts and of Medicine of the University of Dublin, and a Fellow of the Royal College of Surgeons. He is also a Demonstrator of Anatomy in the School of the College, to which position he was appointed when—in consequence of the closing of the Medical College attached to Stevens's Hospital—he ceased to be Lecturer in Anatomy in that College.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 27, Madras 32, Paris 24, Geneva 20, Brussels 24, Amsterdam 22, Rotterdam 20, The Hague 23, Copenhagen 24, Stockholm 25, Christiania 16, St. Petersburg 30, Berlin 33, Hamburg 26, Dresden 28, Breslau 32, Munich 32, Vienna 26, Prague 39, Buda-Pesth 32, Rome 29, Turin 24, Venice 21, Lisbon 23, New York 28, Brooklyn 22, Philadelphia 19, Baltimore 18.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 11, 1883.

THE HARVEIAN ORATION.

THE exigencies of the occasion annually created in connection with Harvey's commemoration by the Royal College of Physicians, are usually met in a manner to which custom has habituated us, but to which it is nevertheless possible to take exception. It is no doubt a pleasant and excellent thing to repeat each year, under official sanction, and in presence of the most responsible officers of medicine, the great and enduring truths on which modern physiology and pathology are mainly based; but notwithstanding, we still hold the opinion, more than once formerly expressed in these columns, that higher honour would be paid to those whose memory is so sought to be perpetuated, by assisting and detailing researches founded on their labours, rather than by mere reiteration of their acknowledged merits.

As an example of orations laudatory of Harvey and his immortal discovery, Dr. Habershon's address, delivered on Wednesday week, is undoubtedly interesting and able; but we must be permitted to question the prudence of his reflections on the value and bearing of what he prefers to regard as simply speculative, rather than deductive, studies. Dr. Habershon has, in our opinion, endeavoured, most unnecessarily, to reprove those who indulge the spirit of investigation untrammelled by considerations of expediency; and his introduction of the religious element into what must be regarded as most purely scientific work—though done, we would hasten to assure ourselves, with the most admirable intention—was, we imagine, ill-advised, and calculated to weaken the force of his most pertinent observations. It is at least premature to declare the inutility of arguments, as to derivation, that rest on partial observations in development; and by arbitrarily refusing to accept any conclusion based on comparative studies, Dr. Habershon subjects himself to almost justifiable attack as an obstructionist. It is, however, pleasant to reflect that nothing which was said by him in his address will, in any way, diminish the respect and consideration felt towards one who has done so much for medicine in all its relations. Strong convictions will naturally impel their holders to give expression to them, and in the strength with which they are held is the principal reason for their utterance on those occasions when especial weight may be held to attach to what is said. For the same reason we are most heartily grateful to Dr. Habershon for the unmistakable manner in which he defended the experimental method in research. Coming from him especially, should such counsel be effectual for good; for none can ever accuse him of too hasty leanings with those whose first application in search of truth is to Nature and natural objects. We have oftentimes of late congratulated ourselves in the thought that the mere brute opposition to scientific advance is giving way to rational acceptance of more ennobling views; and once more would we assert a conviction that the greater part of this wholesome reaction from the stupor created by interested agitation is due to the enlightened efforts of leading members of the medical profession itself. No statement indulged in by the Harveian Orator for 1883 is truer than that which says: "To stop the advance of science is to encourage the darkness of ignorance;" and with all kindliness and respect we would venture to ask whether, by suppressing the spirit of inquiry when it chances to stray in the paths lighted up by theory only, is not in some sort to be guilty of the very practice condemned in the pithy sentence above quoted?

◆

F.R.C.S.I. (HON. CAUS.).

THE Council of the Irish College of Surgeons has decided to grant the Honorary Fellowship of the College to Dr. Crawford, Director-General of the Army Medical Department, and to Sir J. A. Hanbury, Principal Medical Officer during the Egyptian campaign, a proceeding which we predict that both the College and the two Honorary Fellows elect will one day feel to be unwise under all the circumstances, and inconsistent with the dignity of the College and of the two distinguished officers whom the Council proposes to honor.

Those who have read our comments on the conduct of the late campaign—on the evidence produced before Lord Morley's Committee, and on Sir William MacCormac's report—must certainly acquit us of any want of appreciation of the services rendered by the Army Medical Department, or any lack of sympathy for the heads of that Department in the injustice which public opinion did them when the attempt was made to lay the shortcomings of other departments to their charge. We believe that the medical service of the campaign was admirably discharged; that Dr. Crawford and Sir J. Hanbury deserve much credit for its success; and that the attempt to make them the "scapegoats" of the occasion reflected discredit only upon those who made the attempt.

Nevertheless, we dissent from the proposition to make them Honorary Fellows of the Irish College of Surgeons, because, in our opinion, that distinction was not created for successful heads of departments, and, if it were, the granting of it at the present moment bears rather the aspect of a splenetic demonstration against Sir Garnet Wolseley than a calm and judicial declaration that these gentlemen have specially merited the highest distinction which it is in the power of the College to bestow.

The authority of the Council to grant the Honorary Fellowship is defined by a Bye-law which is of the same force for the time being as the Charter, and which states that—

"It shall be lawful for the Council to elect as Honorary Fellows such persons as have eminently distinguished themselves in the science of surgery or in any of the branches of knowledge auxiliary thereto."

It would seem evident that the Council is here limited strictly to the consideration of the scientific attainments of the candidates in immediate relation to surgery as the ground for a grant of the Honorary Fellowship, but we do not see how success as an administrator of a public department can be said to come within the limits of the by-law nor even if its wording be strained so as to include sanitation as one of the "branches of knowledge auxiliary to surgery," can we suppose that any one will allege that the good health of the Egyptian army was the result of special erudition in scientific sanitation on the part of the heads of the Medical Department. We do not suppose that either of these gentlemen would consider that they have a claim to the Honorary Fellowship of a College of Surgeons in respect of their having "eminently distinguished themselves in the science of surgery," although the high position which they have gained is evidence that in this respect they are on a level with any surgeon in the Army; and, for these reasons, we cannot but look upon the grant to them of the F.R.C.S.I. (Hon. Caus.) as a straining of the law of the College and contrary to the intention of those who made that law. We had hoped that the day had passed in the College for decorating any man for any other reasen whatsoever save his scientific character in special relation to surgery, for we hold that the College has discredited itself in times past by the liberality with which it issued its Honorary Fellowship to eminently respectable persons whose position enabled them to be useful to the College or to individuals, but whose names have long since been forgotten. It is true that many years ago the College did co-opt many of this class, but we believe the feeling arose that little honour accrued to great anatomists, surgeons, and physicists by appearing on the same list with useful nonentities; and for many years no such person was admitted to the Honorary Fellowship. The last recipients were—William Bowman, James Syme, Edmund A. Parkes, Samuel Haughton, and Helmholtz; and we think the College honoured itself by such choice, and that the Council would do well to extend this list of noble names rather than dilute it with those of gentlemen whose distinctions, whatever they may be, are neither surgical nor scientific.

If it were considered desirable to give the F.R.C.S.I. (*hon. caus.*) to Dr. Crawford and Sir J. Hanbury, we think that discretion and good taste should have induced the Council of the Irish College of Surgeons to allow an interval to elapse after the dinner in Dublin to Lord Wolseley before making this demonstration. The Army Medical officers in Ireland had clearly demonstrated their views about Lord Wolseley's attitude towards the Medical Department by conspicuously absenting themselves from this banquet, one only of their strength having been present in addition to Sir Robert Jackson, whose old and intimate friendship with Lord Wolseley is sufficient justification for his presence. The military surgeons serving in Ireland, in fact, had deliberately "snubbed" Lord Wolseley, and we think they were right to do so, but we do not think the College right in taking sides in this quarrel at the present juncture. It is to be recollected that the *pros* and *cons* of the dispute between the combatant and medical departments are still undecided, and that the case is *sub judice*; and it would have been well, we think, for the College to leave the affair as it stands, and to refrain from joining in the slight to an Irishman and a great General, however much that slight may have been deserved.

The vote of the Council, coming as it did within a few days of the Wolseley banquet, will give occasion for the insinuation that the Council has acted in haste and ill-temper, and it will necessarily be felt that Honorary Fellowships granted under the influence of such feeling would reflect little honour on the recipients.

◆

THE GROCERS' COMPANY PRIZE PROBLEM.

WERE it not that a scientific committee of such acknowledged competency as that which advises the Grocers' Company in connection with its new scheme for promoting research, has formulated the problem to be solved by competitors for the £1,000 discovery prize, there might possibly appear room for doubting the feasibility of the task thus set. Drs. Burdon Sanderson and George Buchanan, Prof. Tyndall and Mr. John Simon have drawn up the following as the subject of competition for the first quadrennial prize:—"To discover a method by which the vaccine contagium may be cultivated apart from the animal body in some medium or media not otherwise zymotic, the method to be such that the contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product, after any number of such generations, shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymph."

The successful fulfilment of these requirements, when it is attained, will confer upon humanity a benefit of absolutely incalculable proportions. It will at once deprive the operation of vaccination of every single drawback, real or imaginary, which now attends it; and the fortunate recipient of the promised reward will deserve to rank immortal with Jenner himself. Whether the difficulties of the task are of a nature too onerous to be overcome under conditions of existing knowledge it would as yet be rash to affirm, for no one could have anticipated the progress that has, thanks to Pasteur and Koch, been made within so short a period as the last three years in the direction of preventive inoculation with cultivated virus. Undoubtedly the obstacles to be overcome are of no ordinary description, but then the means of investigation freely given to the world as the result of recent researches provide determined observers with hitherto undreamt of possibilities of examination.

We might, perhaps, very fairly insist that opportunities for solving some part of the problem have not been made due use of; that the resources offered by extensive isolation hospitals and plentiful material might have been turned to more account than they have been as centres of merely clinical observation; but in presence of the well recognised and apparently insuperable physical obstacles to any definite research apart from bedside work, there has probably been at least a pardonable shrinking from so laborious and uncertain a study on the part of those directly concerned with administrative duties. Now, however, we may be allowed to anticipate that no scruples of expediency will deter our own countrymen from striving to win for England the distinction that will accrue to the nation which contributes the winner of the discovery prize. Apart from the pecuniary element, considerations of the highest and noblest the human mind can entertain combine to make the goal held in view one worthy of being sought by the most disinterested searcher after truth; whoever shall succeed in reaching it will be not simply the laureate of the Grocers' Company, but a benefactor whose claims will receive ungrudging and eternal recognition.

It would be well not to ignore the necessities that will be imposed on intending competitors for the prize. Experimentation, and that of the most extensive description, is a first desideratum and; inoculation experiments will hold a prominent place in the series. Trained microscopists, also, can alone hope to approach the problem with any prospect of success; for little as we know at present of the virus in question, it is fairly well established that in dealing with it we are in presence of particulate elements less than the twenty-thousandth, and probably not more than one hundred-thousandth of an inch in diameter. The conditions under which these spherules live and increase we know at best but vaguely; of the absolute terms of their life and surroundings we are entirely ignorant. They do not even offer facilities such as the bacilli present; and as far as real information of them is concerned the pages of scientific history where they find description is little more than a blank. But who can say what altered sentence must be written in lieu of these dispiriting ones when four years hence the work of many men devoted to elucidation of this most difficult problem shall have been published to the world? Our faith is strong; but stronger even than faith itself is the assurance borne of experience that when earnest effort is directed by trained intelligence towards the amelioration of human suffering, the great-hearted devotion of scientific enthusiasts is all sufficient to the conquest of difficulties that bar the way to progress and prevention.

Notes on Current Topics.

The Political Weakness of Doctors.

In an able address delivered at the annual meeting of the Midland Counties Branch of the British Medical Association, Dr. Balthazar Foster enlarged upon "the Political Powerlessness of the Medical Profession," which he illustrated forcibly by the length of time which it has taken to push the Medical Reform Bill into the position in which it now stands, and by the little regard which has been shown for the profession in the construction of that measure. He pointed out that every Bill which affects medical men is settled as the public or the agitators please, without the doctors being seriously considered in the matter, and he points out with truth that this state of things arises from the fact that the doctor who thinks it worth while to sacrifice anything of his own interest to public or professional advantage is one in a thousand, and that the great majority of medical men are utterly devoid of public spirit of any kind. We can entirely confirm the justice of Dr. Foster's criticism. It could not be reasonably expected that medical men would neglect their business for public reasons, because few of them can afford to do so, but they might do much which they do not do, and might evince an interest in medico-political matters which, without loss to themselves, might enormously increase their personal importance and the influence of our profession as a body. It is very discouraging to see medical men in election times following a political shibboleth in total forgetfulness of the important legislation in which they are most interested. The thraldom of party would seem to overwhelm all other considerations, and we see men who know little and care less for general political questions voting for any puppet which their "party" chooses to stick up for their adoration, an obedience which their "party" immediately repays by contemptuously ignoring their views on any and every occasion.

St. Andrews Graduates' Association.

The fifteenth annual session of this association was held in the rooms of the Medical Society of London, on June 30th. The treasurer's report showed a very flourishing condition of the funds. The council report congratulated the members on the avowed intention by the Government to withdraw the clause in the Universities (Scotland) Bill by which power was to be given to the commissioners to dissolve the University of St. Andrews, and also on their purpose to retain a representative of St. Andrews on the Medical Board for Scotland. Stress was laid on the need of close union so that every effort might be made to retain and to extend the medical faculty of the university, and promise was given of an early meeting to consider the best means of aiding the university and the claims of the medical faculty by a money contribution from the graduates and their friends.

The anniversary dinner was held at the Holborn Restaurant where an excellent repast was served. Dr. Richardson was in the chair. Among the visitors were Lord Balfour of Burleigh, Sir Joseph Fayrer, LL.D., K.C.S.I., Dr. Hassall, and Dr. Hayward; and among the numerous graduates were Drs. Seaton, of Sunbury, Cholmeley, Cleveland, Cooper Rose, Royston, J. Sedgwick, of Borough-Bridge, Watkins, Murray Lindsay, of Mickleover, Semple, Paul, Hicks, of Hendon, Stamper, of Pembroke Dock, Cargenven, of Derby, Longhurst, and Leonard Sedgwick.

The following officers were elected for the ensuing year :—*President of the Council*, Dr. Richardson, F.R.S.; *Treasurer*, Dr. Paul ; *Secretary*, Dr. Leonard Sedgwick ; *Council*, Drs. Archibald Alderson, Byass, Cholmeley, Christie, Cleveland, Corner, Crosby, Dale, A. G. Davey, J. G. Davey, Davies, Gillespie, C. Gordon, C.B., Griffiths, Henty, Hicks, Hill, Hood, Kesteven, Murray Lindsay, Lipscombe, Longhurst, W. Menzies, Professor Pettigrew, F.R.S., Drs. Pocock, Royston, Seaton, J. Sedgwick, Semple, South, Stamper, Tibbitts, Wilkinson, Willett, Rhys Williams, and Wyman.

Conversazione at the Royal College of Physicians, London.

The annual *conversazione* at the Royal College of Physicians is always an event of great interest ; and the most recent of these gatherings, held on Wednesday last, was in no way inferior in point of attraction or of the numbers attending it to those of previous years. Among the distinguished visitors who accepted the invitation of the President and Fellows were H.R.H. the Duke of Albany, Lords Denman, Crewe and Chelmsford, Bishop Macdougal, the Solicitor-General, Archdeacon Bathurst, Sir A. Watson, Sir C. Locock, Sir James Paget, Sir Spencer Wells, Sir W. Smart, Sir Risdon Bennett, Professor Huxley, Sir W. MacCormac, and many others. Much interest was shown by those present in the objects of art and science exhibited in the rooms of the College building, which had been prepared with much care and taste for the reception of the guests. A very considerable collection of pictures, lent by various owners, and including both oil and water-colour paintings, received a large share of attention ; but special interest was excited in some very beautifully-executed specimens of Berlin cast iron which Dr. Braxton Hicks had lent. These elegant works of art included several historical pieces and personal ornaments, all of which very fully deserved the admiration bestowed upon them. Among the more purely scientific exhibits, Dr Heneage Gibbes' specimens of bacilli of tubercle, anthrax, &c., claimed a good deal of attention, as also did numerous other equally interesting objects of a more or less strictly scientific character. Throughout the evening the Royal Artillery band, which was stationed in the hall of the College, and performed an admirable selection of music, helped to make the *soirée* completely enjoyable ; and the affair passed off with, in every way, entire success.

M. L. de Wecker (*Comptes Rendus*) shows that the infusion of the seed of the jequirity (*Abrus precatorius*) contains a bacillus which, if applied to the human eye, produces purulent ophthalmia. This is the first instance of the transmission of an infectious disease by a plant.

The Contagious Diseases Acts.

It is not yet definitely settled what course Her Majesty's Government will pursue with regard to the difficulties in which they were placed by the recent vote in the House of Commons, but Sir H. Wolff has given notice that he will move the rejection of the Detention in Hospitals Bill, which was officially referred to as a substitute for the Contagious Diseases Acts. We have reason to believe, however, that the Government have no serious intention of pressing this measure, as the military authorities are of opinion that it would be of little use as a substitute for the Acts.

The Irish Union Officers' Superannuation Bill.

The following memorial has been presented to the Chief Secretary by Dr. Jacob, as President of the Irish Medical Association, and has been followed up by a memorial of similar import from the Irish Poor-law Officers' Association :—

To the Right Hon. George Otto Trevelyan, M.P.,
Chief Secretary for Ireland.

The Memorial of the President and Council of the Irish Medical Association sheweth :—

That Memorialists represent a large body of deserving public officers who are deeply interested in the passing of the Union Medical Officers' Superannuation (Ireland) Bill, now standing for a second reading in the House of Commons.

That Memorialists have observed with much regret that, notwithstanding that the Bill was fully examined by a Select Committee in the last session of Parliament, and amended in conformity with the recommendations of that Committee, it has not yet made any progress towards passing into law in the present session.

That Memorialists have reason to believe that the opposition to the measure is limited to a very few members, and that it would receive the united support of the great majority of the representaitves of all parties in the House of Commons, if submitted for a second reading at an early date.

Your Memorialists therefore pray that her Majesty's Government will take the earliest occasion to press forward the Bill, and thus satisfy the just claims and expectations of the union officers of Ireland.

Signed on behalf of the Irish Medical Association,
Archibald H. Jacob, President.
John H. Chapman, Hon. Sec.
June 24th, 1883.

We are glad to say that the outlook of the Bill is, in consequence, more encouraging.

The death-rate from diseases of the zymotic class continues very low throughout the United Kingdom. With the exception of measles in one or two towns, there is almost an immunity. Glasgow, Newcastle, and Liverpool have an excess of this disease, and scarlet fever prevails at Sheffield, but elsewhere there is nothing to report. The highest annual death-rates from measles were 2·1 in Liverpool, and 4·9 in Newcastle-upon-Tyne ; from scarlet fever, 1·3 in Leeds, and 4·1 in Sheffield ; from whooping-cough, 1·4 in Plymouth ; from "fever," 1·0 in Bolton. There were but 26 deaths from diphtheria in the 31 large towns, of these 15 were in London, and 3 in Glasgow. Small-pox caused 4 deaths in London, 2 in Birmingham, 1 in Manchester, and 1 in Newcastle-upon-Tyne, but none in the other towns.

Chelsea Hospital for Women.

On Saturday last, the handsome and commodious new building erected in the Fulham Road, and destined to be the future home of the Chelsea Hospital for Women, was officially inspected by the Committee of Management and a number of gentlemen invited to be present on the occasion. The arrangements of the hospital have been devised and carried out with the utmost consideration for the comfort and convenience of its inmates; and it cannot fail to be a source of unbounded satisfaction to those whose efforts have been thus successful, to find themselves on the eve of substituting so thoroughly useful and completely equipped an establishment for that in which the operations of the hospital have hitherto been carried on. The new building contains 65 beds, and no ward is to be tenanted by more than nine patients. The fittings are simple, but are even elegant in comparison with the customary surroundings of a hospital ward, attention being especially attracted by the exceedingly pretty and useful bedside cupboards provided throughout the hospital, and which have been specially designed by Mr. Oetzmann, to whom the contract for furnishing has been entrusted. A valuable feature of the building is the provision of two balconies at one end of it, from which far spreading and delightful views over south London as far as and including the Crystal Palace, are obtained, and which will afford a grateful means of outdoor enjoyment to those patients who may be well enough to take advantage of it. The operating theatre is a commodious and well lighted chamber, and is situated in close contiguity to the lift, so that with the least possible delay patients can be taken to it from any part of the hospital. The least satisfactory part of the building is that devoted to post-mortem work. This is a small room built away from the main structure, and *decorated* with a profuse liberality; but withal, so contracted in dimensions that anything beyond the most desultory autopsies will be impossible within it. The kitchens and store rooms are large, airy, and well arranged; and the dormitories, &c., for resident staff, are all that can be desired. After the inspection a lunch was provided, over which Mr. J. Wright-Biddulph, J.P., presided, and which was followed by the delivery of speeches from the Chairman, Sir. Algernon Bothwick, Bart., Mr. Ernest Hart, Mr. Jas. Debac, treasurer, and the Hon. and Rev. Francis Byng. From the treasurer's statement it appears that the hospital is, financially, in a satisfactory condition. The new building and furniture cost £18,082, and there remains on hand a balance of £400, exclusive of £600 invested separately on account of the Samaritan Fund. Altogether, the charity is in a prosperous condition, and starts on its fresh career of usefulness under the most promising auspices.

Mr. Peter Spence, the eminent practical chemist, died at Manchester on Friday last. He discovered the process of the extraction of alum from the refuse shale of collieries and the waste ammoniacal liquor of gas works, which revolutionised the trade, the cost of production being permanently reduced by 40 per cent. Deceased was 77 years of age. His name will be handed down to future generations in connection with "Spence's metal."

Lord Wolseley on the Medical Service.

Not a little curiosity was felt by those interested in maintaining the fair fame of the Army Medical Department to learn in what fashion Lord Wolseley would refer to this branch of the profession, when the opportunity of reviewing its services once more presented on Thursday last. On this day General Wolseley distributed the prizes gained by students of Charing Cross Hospital Medical School, and delivered the address customary on such occasions. In this he was at pains to eulogise the earnestness, devotion, and valuable labours of officers of the Army Medical Department in a way that cannot fail to be flattering to them, but which is also singularly at variance with the remarkable evidence given by him before Lord Morley's committee of inquiry. We may, however, very willingly overlook Lord Wolseley's recent utterances now, since he has conclusively demonstrated that they were the outcome neither of experience nor reflection. When experience was recent he wrote in highly laudatory terms of the medical service; and after reflection he tenders equally worthy testimony. It was only when neither of these aids to conclusion was invoked that the leader of the Egyptian campaign showed an inclination to depreciate and condemn the work of the profession during the war.

The Society of Arts' Conversazione.

Sir William Siemens, the Chairman of the Council of the Society, will receive the members of the Society at a *conversazione* to be held in the buildings of the International Fisheries Exhibition on Wednesday, the 25th inst. Their Royal Highnesses the Prince and Princess of Wales have intimated their intention to be present.

New Professional Honours.

No one who has been brought into relation with the Registrar of the Royal College of Physicians of London will fail to appreciate the peculiarly graceful compliment paid to so highly respected a member of the profession in the bestowal of a knighthood on Dr. H. A. Pitman. Those who have advised this mark of Royal favour have not without full cause gauged the satisfaction which such distinction, so conferred, would excite throughout the profession generally; and we are personally much gratified to have the opportunity of congratulating Dr. Pitman on the well-deserved honour he has received. It would be affectation to ignore, however, that Dr. Pitman's services to medicine have been less in the way of actual scientific industry than in the direction, no less valuable in many ways, of social and personal influence. His contributions to literature, and his assistance to practical medicine would not in themselves, of course, have entitled him to look for the reward he has obtained; but in other paths of usefulness and devotion he has undoubtedly achieved that which is not inappropriately recognised by the bestowal of a knighthood.

At the same time that Dr. Pitman's elevation to the titular ranks was announced, a similar distinction to Mr. Edwin Saunders, F.R.C.S., Dentist to the Royal Family, was gazetted, and in this case also the reward is one for long and faithfully-rendered services, and will be so hailed by the professional brethen of the recipient.

The Election at the Royal College of Surgeons of England.

THE annual election of members of Council of the Royal College of Surgeons, held last Thursday, resulted, after a keen contest, in the return of Messrs. Cooper Forster and Sydney Jones, and Sir William MacCormac, this order being observed in the votes polled by each. It is thus seen that neither provincial candidate succeeded in obtaining votes sufficient to give him a position among the elected; and also it is seen that the claims of Sir William MacCormac have been regarded as superior to those of Mr. Lawson by a majority of Fellows. We do not disguise that this result is a disappointment, nor that under circumstances like those surrounding the recent election we could have been better satisfied to see a greater deference paid to seniority, especially since no possible arguments could be adduced to favour preeminence of a particular candidate over his senior competitors. How far the result will affect the future of course remains to be seen. We can, at any rate, feel that the success achieved by Mr. Sydney Jones is well deserved and will be fruitful, while Mr. Cooper Forster's re-election was all along regarded as a certain and desirable event.

Telephones for Hospitals.

WE observe with much satisfaction that the Public Health Committee of the Dublin Corporation has taken up the suggestion which we offered to them some weeks since, and has resolved—"That the secretary be instructed to inform the managing committees of the various hospitals subscribed to by the Corporation that this committee considers it desirable that they should be placed in telephonic communication with their medical staffs, after the manner of Continental hospitals." The Public Health Committee is the department of the civic administration whose function it is to report upon the votes which the Corporation should make to the Dublin hospitals, and its recommendation has, therefore, a somewhat mandatory force. The grants made last year from the corporate funds included the following:—

Meath Hospital	£300
Cork Street Fever Hospital	300
Rotundo	450
Coombe	520
Incurables	300
St. Mark's	100

And, no doubt, the recommendation of the Public Health Committee will have its effect with the institutions thus subsidised. We hope to see the Hospital Sunday Fund Council equally appreciative of the advantages of telephonic connection between the hospitals and their surgical staffs, and that they will at the coming meeting of the Sunday Fund confirm the suggestion offered by the Public Health Committee. The only objection which could be urged to incurring the expense of telephonic communication with hospitals has been recently removed by the announcement by the Telephone Company that they now keep their offices open night and day. This expansion of the usefulness of the "Exchange" is now extended to Sundays, so that under the new arrangements the surgeon who "joins up" will have continuous communication with his hospital at all times and hours of the year.

We regret to hear that a selfish and stupid opposition to the project of hospital intercommunication in Dublin has been evinced not only by a few Governors of the antique and musty type, but by a few medical officers of the "take-it-easy" class. These gentlemen do not want to be bored by being told at unseasonable hours how their patients fare, nor to be troubled between the periods of their hospital visit whether their patients live or die. This class of practitioner is a trifle too conservative and too fond of their comfort to make good hospital surgeons, and the public will probably say that functionaries who do not wish to know anything of their cases for twenty-four or forty-eight hours at a stretch would do better to relieve themselves of their irksome hospital duties, resign into private life, and leave their functions to more advanced and advancing men, who feel that they cannot by any possibility know too much of their patients. It was men of this class who for many years resisted the appointment of house-surgeons in Dublin; but they had to yield under pressure of public opinion, and they will also have to do so in reference to telephonic communication.

We hear it rumoured that the Board of Superintendence of Dublin Hospitals will also report in favour of this improvement in the means for caring for the sick poor, and will thus bring the State-supported hospitals under the same pressure as the civic subsidised institutions now are.

Cholera Phases.

FOR the existence of cholera in Egypt the British Government is being roundly abused by certain sections of the Italian and French press, the latter insisting that if that country had been still under French control, the plague would not have appeared. This is a new phase of sanitary politics; hitherto, the world had not discovered the fact that the French presence in any part was a sufficient prophylactic for disease. It is well to learn the truth, however, even in misfortune, and for the poor Egyptian we can only offer our commiseration. Doubtless, also, her Majesty's Government will be glad to clear out the remaining British soldiery when it is pointed out to them that French control is so much to the moral and material advantage of that afflicted country. Meanwhile, the Paris Hygienic Council have taken the initiative of calling a medical committee together for the purpose of revising the existing cholera instructions should the disease appear in that city. This committee consists of Drs. Pasteur, Dujardin-Beaumetz, Loiseau, Lagneau, Bouchardat, and Bourgoin. We congratulate our neighbours on this very sensible and timely initiative; and should cholera not visit that capital, which we sincerely hope, the committee might find ample scope in endeavouring to check the spread of typhoid, which is always endemic in their midst, and at the present time also epidemic.

THE French Government, in acknowledgment of the merits of Professor Pasteur, have increased his pension from £450 to £1,000 yearly, and extended it to his wife should she outlive him.

Dr. George H. Kidd, M.A.O. Dub. Univ.

The University of Dublin has done itself honour in selecting Dr. George H. Kidd for the grant of the honorary degree of Magister in Arte Obstetricâ. The entire voice of the profession in Ireland applauds the act of the University, and declares Dr. Kidd well deserving of the highest distinction which can be bestowed. Risen from the ranks by force of will, intelligence, and industry, the new honorary M.A.O. is known throughout Europe not as a mere executive machine, or an eminently respectable public officer, but as a pre-eminently distinguished and thoroughly skilled surgeon. Therefore, honours conferred on him bear favourable comparison with the distinctions offered by other bodies to persons unknown outside their own localities and departments. The following public oration delivered by Professor Webb on the occasion of the granting of the degree was a gem of Latinity, witty and classic, and worthy of the occasion :—

"Et nunc mihi, Juno Lucina, fer opem! Ingenio parturienti meo adsis, precor; nam celebrandus adest castus ille sacerdos qui cærimoniis ac sacris tuis summâ cum religione præesse solet. An me ludit insania poetæ?

> Continuo auditæ voces, vagitus et ingens
> Infantum—

non infantum, ut in inferis,

> Quos dulcis vitæ exsortes, et ab ubere raptos
> Abstulit atia dies—

sed quos favente Junone suâ, ad auras produxit Artis Obstetriciæ Magister ille noster. Illius natalibus affulsit signum synonymum Hædorum—splendor, ut ferunt, pluvialis, sed quod de Danae refertur, pluvialis auro. Arti Obstetriciæ aliquid debemus omnes Artis præcipuæ magistrum præcipuum salutemus universi."

"Vote No. 4."

A good deal of disappointment at the delay that has already occurred in connection with vote No. 4 of the Army estimates finds expression among medical officers in the larger garrisons, and hints are even being heard as to the particular object with which the vote in question is kept back. We hesitate to believe that the delay is in any way directed towards the medical department as a separate part of the military services. But, inasmuch as the occasion of this vote is confidently looked to as affording an opportunity to rebut many at least of the accusations made against that department, and against certain individual members of it in Egypt, we trust that, in the interest of all concerned, the subject may speedily be brought under discussion in the House of Commons. It is particularly undesirable that a body of men who feel collectively and individually that unjustifiable accusations have been made against them should further be led to believe that delays are purposely being created in order to postpone as long as is possible the full exposure of fallacies which they hope and believe they can make manifest.

Both diphtheria and measles are very prevalent in Berlin just now, deaths in the former registering fifty per cent. more than from the same cause in the whole of the United Kingdom. Typhoid is also present in Paris and in St. Petersburgh.

Royal Irish University.

The medical examinations of the University terminated on Friday last, and the "mortality" amongst candidates is said to have been excessive. Of 72 who presented themselves for the first half, or primary examination, 35 were rejected—48·6 per cent. For the second, or final examination, 45 offered themselves, of whom 27 failed to get through.

We are very glad to judge from these figures that the University is disposed to pursue the far-seeing policy of making its degrees respected and sought for, than the temporary expedient of passing a crowd of half-educated men in order to make a show of business before the public. If the University keeps up its examination standard, it will fulfil its function in the best way, and if it follows up that course by similar strictness in ensuring that the education of the candidate is *bona fide*, its degrees will at once command confidence. We hope the Senate will recollect that there are such things in Dublin as sham roll-calls, night lectures and false certificates, and will be independent enough to crush out these dishonest methods of making money, at least as far as R. I. U. students are concerned.

M. V. Burq (*Comptes Rendus*) confirms the reported immunity of workers in copper from cholera and typhoid fever. The *Bon Accord* trade society, consisting of 300 to 400 bronze-turners, fitters, &c., has not, since its foundation in 1819, lost a single member by either of these diseases.

A Parliamentary paper just issued contains an account of receipts and expenditure of the Royal University of Ireland, between October 1st, 1881, and March 31st, 1882. The receipts amounted to £10,365 5s., and the expenditure to £2,162 19s. 8d., leaving a balance, including £7,000 on deposit in bank, of £8,202.

The *Globe* is informed that the Charing Cross Hospital Volunteer Ambulance Corps, which is entirely composed of medical students attached to that institution, who were inspected by Lord Wolseley on Thursday last, have volunteered to go out to Damietta under the command of Mr. Cantlie, F.R.C.S., for the relief of those suffering from cholera.

At a meeting of the Council of the Royal Society, last week, Professor Huxley was chosen as president in the place of the late Dr. Spottiswoode. The *Times* remarks that the selection will be received with satisfaction, not only by men of science, but by that outer world of education and culture which judges more accurately and clearl than do specialists the claims of diverse merit.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were — Portsmouth, Birkenhead, Brighton 13; Bristol 14; Norwich, Hull 15; Leicester, Plymouth, Cardiff 16; Bradford, Oldham, Nottingham, Leeds, Derby 17; Bolton, Halifax, London 18; Preston 19; Sunderland, Edinburgh, Sheffield, Salford 20; Wolverhampton, Birmingham 21; Blackburn 22; Liverpool 23; Huddersfield 24; Newcastle-on-Tyne 26; Dublin, Manchester 27; Glasgow 28.

Irish Graduates' Association.

Mr. William Stokes, Professor of Surgery, Royal College of Surgeons, has been nominated President-elect of the Irish Graduates' Association. The next meeting will take place at Liverpool during the first week in August.

We are informed that Dr. Reginald Southey has been appointed a Commissioner in Lunacy, in the place of Dr. Robert Nairne, who has resigned his office.

◆

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

The Medical Bill and Dr. McCall Anderson.—Under this heading the Scotch correspondent of a leading contemporary makes the following astounding observations :—"Professor McCall Anderson's statement, going for the entire rejection of the measure, has struck a most sympathetic chord among Scotchmen generally." It must not be supposed that in giving this statement a most unqualified contradiction that we are of "the well-paid agitators of the convicted Corporations." The truth is that Dr. MacCall Anderson's letter to the *Glasgow Herald* came upon the profession with no little surprise, for it was generally felt that a discreet silence would have become him, of all men ; and considerable forbearance was displayed in allowing the singular production in question to pass practically unnoticed. The "sympathetic chord among Scotchmen" which Dr. Anderson's epistle struck was this—the perfect recollection of the irregular institution of the chair, which so far as *that* is concerned, he worthily enough occupies, and the hollowness of the commiseration for the unfortunate medical student which, in view of operations at the University, he expresses. The students are already so poor, he blandly informs the public, that it would be iniquitous to impose another examination upon them ; and yet Dr. Anderson is one of those men who, within the past fifteen years, have extended the medical curriculum at the University of Glasgow from *thirteen* to *twenty-six* classes, and augmented the cost from £46 4s. to £90 6s. Nay more, for Dr. Anderson, *public money bought* a suite of skin wards in the Western Infirmary, for which surely the public might reasonably enough expect that the future race of medical men would be initiated into the mysteries of dermatology ; but what happens ? The student desirous of special instruction in skin diseases must needs resort to the Skin Dispensary to obtain it, and that at a cost of £2 2s ! Now we leave our readers to estimate the value of Professor MacCall Anderson's 'commiseration" for the student, and we would have refrained from noticing these matters but for Dr. Anderson's "good natured friend (?)" the Scotch correspondent of our contemporary. It were vain to deny that on the part of the Scotch professors and their sycophants who have benefited by the present indefensible *régime* "the entire rejection" of the Medical Bill would be hailed with gratulation ; but the Crown has too long extended the ægis of its unjust protection to greed and incapacity ; the present rotten condition must determine, and the voice of sense and justice will command a hearing, and a respectful hearing, in the council of the nation.

The Public and the Medical Bill.—There is one species of the genus "snob" which Thackeray has entirely overlooked. We allude to the "medical snob." We would not be guilty of the affectation of endeavouring to fill the *cadre* which the great master has left vacant, but we would faintly indicate a prominent characteristic of this obnoxious personage. This professional prude proclaims a great horror of the public and of discussing certain questions in public, while at the same time he is the assiduous cultivator of the public by every oblique device conceivable. There are an immense number of questions which it is no less unseemly than unprofitable to discuss in public, but we would say for the rank and file of the profession that it is not they, but the professors at our Universities who are given to transgressing in this manner ; and that if, on the question of "Medical Reform," University professors have addressed themselves to the public in a manner not calculated to enhance the public estimate of their exalted pretensions, the fault is not that of the profession. Of these questions which are neither seemly nor profitable for public discussion that of Medical Reform *is not*. Disguise it as we may, all political power is vested in, and is from the people. The people are the ultimate tribunal in all matters of legislation. The pending medical legislation is not for the profession, it is for the people ; and it is by the representatives of the people that the measure will be passed or rejected. The discussion of the question of Medical Reform is one, then, which is eminently suited for the public. It is perfectly true that on all medical matters ninety-five per cent. of the public are sunk in crass ignorance ; hence the superstition with which they invest all medical matters, and hence they become an easy prey to charlatanism both within and without the profession. The remedy for this is clear—the cure for every form of injustice—viz., instruction and education. We would not, therefore, have medical reformers dissuaded from endeavouring to instruct the public on "Medical Reform" by the priggish and oracular utterances of certain "medical correspondents." Surely the iniquity of a State-instituted monopoly in the matter of medical education is of more easy comprehension by the public than the mysteries of the renal secretion of a moribund archbishop !

Edinburgh.—The Disgraceful Theatre Disturbance.—A meeting of the Senatus Academicus of the University of Edinburgh was held on the 3rd inst., for the purpose of receiving the report of the committee that had investigated into the circumstances attending the disturbance in the gallery of the Theatre-Royal, as reported in our last issue. The students in question put in appearance at the time appointed to hear the decision of the Senatus, when the following announcement was made :—"University of Edinburgh. — The under-named students having been convicted of creating a disturbance, and of other misconduct at the Theatre-Royal on the evening of Thursday, June 28, have, on the report and recommendation of the Principal and Dean's Committee to a special meeting of the Senatus Academicus, been sentenced as follow :—Edgar Samuel Sanderson, first-year student of medicine, and Robert Paterson Henderson, second-year student in law, to be rusticated for the present summer session and the ensuing winter session ; and George Sibley Hicks, first year's student of medicine ; Walter Smithies, do. ; Henry Bryan Densham, do. ; Walter Scott, second year's student, and William Owen, first year's student of medicine, to be rusticated for the present summer session.—By order of the Senatus Academicus, 3rd July, 1883."

"Interesting" to the Scotch Corporations.—The subjoined advertisement appears in the "quacks' corner" of the *Oban Telegraph*, a paper in which we regret much to see those effusions, as their continued appearance indicates to some extent that their object is accomplished :—"Interesting to Gentlemen.—I, Dr. Daniel Sutherland, Surgeon at the New Medical Hall, 73 Jamaica Street, Glasgow, hereby intimate to all whom it may concern that I have long studied and treated Confidential Complaints and Weaknesses as a principal part of my Practice, both here and in Edinburgh, though never formerly made known by advertisement, and it is possible this notice may be construed as a breach of professional etiquette; but I think it very pardonable when I consider the number of gentlemen constantly consulting me with their Constitutions injured and Complaints aggravated after being for months or years the dupes of Quacks and Druggists! I consider it a righteous necessity in the Public interest to Advertise the fact that a Member of the Profession proper devotes his time to the study and treatment of these special Complaints. Gentlemen are therefore inexcusable if they fall into the hands of empirical pretenders. I make free to assure Gentlemen entrusting me with their confidence that they may rely upon the highest professional honour and skilled conscientious treatment, whether they visit me at 73 Jamaica Street, Glasgow, or communicate with me by letter, which will have my immediate attention.—I am, faithfully, Daniel Sutherland, Licentiate of the Royal College of Physicians, Licentiate of the Royal College of Surgeons; also of the Faculty of Physicians and Surgeons. For 7 years Councillor and Trustee of the City of Edinburgh, and Manager of the Royal Paternity Hospital, Edinburgh; President of the Scottish Christians' Evidence Society; Medallist (Royal College Surgeons) 1867; awarded Queen's Prize (Science of Chemistry) Kensington Museum 1868; Public Honours (Royal College of Surgeons) 1869, etc., etc." "Dr." Sutherland, according to the Medical Directory, is a Licentiate of the Corporations mentioned, and we commend to their notice the "President of the Scottish Christians' Evidence Society."

Aberdeen Royal Infirmary.—The managers of the Aberdeen Royal Infirmary have issued an appeal to the clergymen and office-bearers of the churches of all denominations in Aberdeenshire and Kincardineshire requesting that steps be taken to provide for yearly subscriptions being obtained by paid or honorary collectors throughout these counties, with a view to prevent further shortcomings in the funds of the institution, and keep the income equal to the expenditure.

Health of Edinburgh.—For the week ending with Saturday, the 30th ult., the mortality in Edinburgh was 84, and the death-rate 19 per 1,000. Diseases of the chest accounted for 38 deaths, and zymotic causes for 8, of which 1 was due to fever and 6 to measles—the intimations of these diseases being 2 and 71.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 30th ult., were at the rate of 28 per 1,000 per annum, against 30 in the preceding week, and 23, 24, and 23 in the corresponding periods of 1882, 1881, and 1880.

The University Court of Aberdeen.—This Court will meet next week, when the resignation of Dr. Ogston will be accepted. The election of the new professor will not take place till the end of August.

Edinburgh University Court.—An order of Her Majesty in Council has been received, approving of the following alteration of Section IX. of Ordinance No. 5, *Edinburgh* No. 2, of the Scottish Universities Commissioners, 1858, under which the said section, as ordered under the authority of a previous order in Council, dated 17th May, 1876, has been deleted, and the following has been substituted therefor:—"That students who profess themselves ready to submit to an examination in the first division of these subjects at the period of examination immediately preceding their second winter session of professional study, may be admitted to examination at that time: Provided always that students who commence their medical studies in the summer session shall not be admitted to a degree in medicine unless their course of study, subsequent to the completion of the summer session in which they commence their medical studies, shall not be less than the minimum course of four years prescribed in Section IV. hereof."

Literary Notes and Gossip.

Again the Boylston prize of the Harvard University has been awarded to an essayist on this side the Atlantic. Last year our contributor, Dr. Dolan, of Halifax, Yorkshire, was the recipient; this year it falls to Dr. P. M. Braidwood, of Birkenhead, for his essay on "The Pathology and Treatment of Measles and Allied Diseases."

⁂

Politzer's "Text-book of Diseases of the Ear" is, we understand, meeting with a rapid sale in the United States, a very large edition being almost exhausted in a few months, the leading American journals having pronounced it "the best work on the subject of aural diseases which has ever appeared." The translator, Dr. Cassells, of Glasgow, will doubtless feel gratified with the result of his labours.

⁂

Dr. Sansom has published (Churchill's) in a neat small 8vo the Lettsomian Lectures he delivered before the Medical Society of London. As these have been fully reported in our columns, our readers are aware of their value. In the volume a few woodcuts illustrate the text, and on the cover is embossed an outline figure of the chest, from which a pencil and paper may be made at any time to give a "rubbing" to serve as a chest-chart.

⁂

The series of Analytical and Therapeutical Reports on the Mineral Waters of Europe, by Professor Tichborne and Dr. Prosser James, which appeared in these columns, have now been reprinted in book form, with additions, among which may be mentioned a chapter on artificial mineral waters. This little work, of about two hundred and fifty pages, will be found a valuable guide to the profession upon the relative values and uses of the various bottled waters, and inasmuch as the analyses are done by eminently competent authorities unconnected with any particular spring, it becomes the most reliable as well as the most modern work on the subject.

⁂

Another new journal on health lines has started this month. If the public would but read one tithe of what is written by our modern sanitarians, the medical profession would become a relic of a barbarous past, and everybody would die of extreme old age. But, fortunately, or unfortunately, many who read do not heed, and those who heed frighten themselves into various imaginings, and the doctor is the result. The public have now plenty to choose from in the way of periodical literature on the subject: the *Sanitary Record*, *Sanitary Engineering*, *Public Health*, *Health*, and the *Health Journal;* the latter two have been commenced during the past few weeks.

⁂

"Kallos: a treatise on the Scientific Culture of Personal Beauty and the Cure of Ugliness." Such is the modest title of a work just issued from the press by a "Fellow of the Royal College of Surgeons." Who the Fellow is, and which of the Royal Colleges he has honoured by his patronage, is left to the thought-reading proclivities of the nineteenth century. We presume, however, that as Irish ladies are proverbially beautiful, and the artifices *à la Madame Rachel* never possessed any attractions for the sensible minds of the ladies of "the Clans o'er the Tweed," that the London College is our author's *alma mater*, and Englishwomen those for whom he writes.

⁂

Much as some might be inclined to doubt it, our author "means Kallos to be studied seriously," and here are some samples of the fare provided for the delectation of the British public. The possessors of coarse lips are counselled to eat less, and those of thin lips to eat more. Persons with wrinkled foreheads must pay "careful attention to the state of the bowels, and local emollients, such as cold cream, applied at night, and followed in the morning by astringent lotions, such as alum, may tend to check the wrinkles which form round the eyes." Our author has not a crumb of comfort for the owners of flat noses. Nature, in this case, must "be the sculptor of their noses;" but for obliquity of nose "the treatment lies in a simple operation,' which, by the way, he omits to mention. Space does not permit us to present the author of "Kallos" with a more lengthy advertisement. Moreover, our readers will probably be content without more of this farrago of nonsense, even though presented by an F.R.C.S.

⁂

Dr. Debout D'Estrees has brought out his "Medical Guide to Contrexéville" in English (Churchill's), in which the reader will find full details of this spa and the value attached to it. The waters of this village in the Vosges have long had a reputation in renal and vesical disorders, and our author believes it has great power over calculi. He is also of opinion that they are well adapted for diabetes occurring in stout and in gouty patients. The waters are calcareous, and the author naively supposes that such should be well understood by English doctors, as from the middle of last century they have been recommended in England, and the British Parliament bought Mrs. Stephen's specific.

⁂

The question often occurs to us as to the relative value of the brain-producing element to its worldly equivalent money. We will take the author as representing one side of the problem, and the publisher the other, and incontinently a modified edition of the parable of Lazarus and Dives rises before us. Last week we learned that the will of Dr. Chambers, the Edinburgh publisher, was proved under £91,000. A short time since the will of Mr. John Churchill, senior, represented about £150,000 in hard cash, and that of Mr. Brown, of the firm of Longmans and Co., about £200,000. Be it remembered that all these commenced life as poor men, and the solution of the problem is that publishers have had, at least in the past, a very fair time of it.

⁂

Dr. Lauder Brunton has brought out a new edition of his "Tables of Materia Medica" (Macmillan), a book which has already made its way as a companion to the museum, its arrangement being such as to afford considerable assistance to the student's memory. The most striking addition to the work is a series of figures of the more important articles in the organic materia medica, which will be of use to students in enabling them to recall the appearance of various substances they have seen; but we would urge upon them to examine each drug, and not be satisfied with an engraving. In fact, it is as promoting museum work that we have most valued Dr. Brunton's tables. Another feature of the new edition is a series of questions on the subject, which will assist the student in finding out what he knows, and in gauging deficiencies.

⁂

The International Encyclopædia of Surgery is having a much greater success on the Continent than in this country, for a very obvious reason. Frenchmen are profoundly patriotic, and are too apt to inquire "if any good thing can come out of Nazareth." Our cousins will doubtless ascribe this to old world bigotry, patriotism and bigotry being not infrequently synonymous terms. Be this as it may, the prospectus was too decidedly American to be acceptable with the profession in France, and the French publishers wisely determined to impart to it more of an International character so far as that country was concerned, and accordingly engaged one or two eminent Parisian pens to carry out the idea. The French edition, therefore, will contain chapters not to be found in the American edition published in London, and a large subscription list is, we understand, the result.

⁂

Under the title of "A Description of the Six Plants required for Botanical Examination of the Royal College of Surgeons, Ireland," has appeared a *brochure* of sixteen pages, designed for the use of such students as may desire to make up a concise and accurate account of the characters which distinguish the half-dozen typical plants upon which the greatest stress is laid in the first professional examination at the Royal College of Surgeons—namely, Ranunculus, Papaver, Pisum, Fragæria, Leontodon, and Digitalis. The several descriptions are very accurate and complete, and if the student will, along with his perusal of these descriptions, refer to the ample glossary of terms, he will find that all the hard names are fully explained in the order of their occurrence. He should also, of course, procure specimens of the several plants, which are all easily obtainable. For the purpose for which it is designed, this little book may be safely recommended.

⁂

Dr. Isambard Owen's "Materia Medica: a Manual for Students" (Churchill's) will be found useful to a large number. As the author confines himself to materia medica, leaving therapeutics, pharmaceutical as well as medical, students will like this unpretending work, which is an admirable supplement to systematic treatises. The leading facts are grouped together with considerable skill, so as to greatly assist the memory. A series of tables formerly published by the author are incorporated in a revised form. Indeed, the volume is of a quasi-tabular form throughout, but is more readily readable than ordinary tables. Thus all the official drugs and their preparations are presented in a series of groups, with the essential facts relating to each. Besides this, there is a synopsis of doses, of compound preparations and their ingredients, and the proportion of active ingredients in the pharmacopœial preparations. The arrangement adopted is often very striking, and altogether we have been pleased with Dr. Owen's book.

⁂

The difficulty experienced in attempting to comply with the request to "Please review" *Tippling Women*, by the Rev. Charles Courtenay, is ample excuse for mentioning this first instalment of "The Taproot Series" among recent literary novelties. An ambitious wish to reclaim from their drinking habits those who have set out on the dangerous path most often incites well-meaning philanthropists to produce such exordiums in type as are exemplified in *Tippling Women*. The good these publications do is, however, doubtful in the extreme; but when, as in the pamphlet in question, medical men are attacked for that they directly provoke to intemperance, it is fair to assume that evidence is the least tangible of the grounds on which the reverend authors of the scandal base their charge. The Church of England Temperance Society has accomplished much beneficent work; it is capable of much more, and this quite as surely with the aid of our profession as without. Baseless attacks on the latter are unworthy of the former.

⁂

If the number (5, vol. i.) of the *American Journal of Physiology* with which we have been favoured is a fair sample of the publication, it must be at once admitted that progress will be a long time yet spelt by its conductors with a small "p." The reputation which Dr. Hughlings-Jackson enjoys may very well content him for such light digressions as the editors of the journal referred to exhibit when repeating his name; or it possibly may be from a prejudiced objection to redundancy that our English specialist is described as "Dr. Hulings Jackson." Even prejudice, however, ought to regard the common rules of grammar, and to abstain from asserting of Koch—unfortunate man—that "He thinks the danger of transmitting syphilis and scrofula *are* infinitesimal." The conductors of the *American Journal of Physiology* would do very wisely by taking as their model for a time, and closely imitating as far as they are able, our English prototype of their periodical, the *Journal of Anatomy and Physiology*, and this, too, no less as regards style and composition than with respect to scientific contents.

⁂

New Books and New Editions.—The following have been received for review since the publication of our last list, June 6th:—The Bastilles of England, by Mrs. Lowe. The Latin Grammar of Pharmacy (2nd edition), by Joseph Ince, F.C.S. The Public School French Grammar, by MM. Brachet, Brette et Cie. The Treatment of Wounds and Fractures, by Sampson Gamgee, F.R.S.E. Hospitals, Infirmaries, and Dispensaries, by F. Oppert, M.D. (2nd edition). Handbook of the Theory and Practice of Medicine (5th edition), by F. T. Roberts, M.D., F.R.C.P. A few Words upon Anæsthetics, by T. Freeman, L.R.C.P. International Encyclopædia of Surgery, edited by J. Ashhurst, M.D. (Vol. III.). Lectures on Practical Pharmacy, by B. S. Proctor (2nd edition). The Mineral Waters of Aix-les-Bains, by Léon Blanc, M.D. The Student's Guide to the Practice of Medicine, by M. Charteris, M.D. (3rd edition). Braithwaite's Retrospect of Medicine, edited by Drs. W. and J. Braithwaite (Vol. LXXXVII.). Guy's Hospital

Reports, edited by H. G. Howse, M.S., and F. Taylor, M.D. (Vol. XLI.). Vichy and its Therapeutical Resources, by Prosser James, M.D. Body and Will, by Henry Maudsley, M.D.

◆

Medico-Parliamentary.

HOUSE OF COMMONS—MONDAY, JULY 9.

THE CONTAGIOUS DISEASES ACT.

In answer to Sir H. Wolff and Captain Price, the Marquess of **HARTINGTON** said the number of women in hospital at the time of the suspension of compulsory examination under the Contagious Diseases Acts was 267, and the number now detained in hospital was 134. If the hon. member (Sir H. D. Wolff) moved for a return of the numbers detained at each station, there would be no objection to produce it.

Captain **PRICE** gave notice that on the second reading of the Hospitals Detention Bill he would move that it was not expedient to repeal Acts which had proved of great value to the health and morality of the public.

THE CHOLERA IN EGYPT.

In answer to Sir H. Wolff,

Lord E. **FITZMAURICE** said—I propose to give to the House a short summary of the information which has reached her Majesty's Government from Sir E. Malet and Consul Cookson regarding the measures taken for preventing the spread of cholera in Egypt. These measures are under the control of the Central Government in Cairo. Sir E. Malet states that the Sanitary Board at Cairo is composed of native and foreign doctors, among whom is Dr. Grant, the medical adviser of her Majesty's Consular Court. They have from the beginning of the outbreak sat every evening, in conjunction with the Minister of the Interior and General Baker; and Sir E. Malet adds that doctors, medicines, and food have been supplied to the infected places, and he expresses the opinion that the Government have done all in their power to stamp out the disease. At Alexandria, Consul Cookson states that a Commission has been working hard in inspecting nuisances and suggesting sanitary measures, and an independent British Committee has been formed to visit the houses of British and Maltese residents in Alexandria. The infected houses have been isolated by cordons of police. With regard to the steps taken by her Majesty's Government, I may state that a departmental committee has been appointed by my right hon. friend the President of the Local Government Board, on cholera precautions generally, and a competent medical authority connected with the India Office is about to be despatched to Egypt, under the direction of the Board.

THE MAILS AND THE CHOLERA.

Mr. **FAWCETT**, in reply to Mr. Smith, said that on Saturday he received information from the manager of the Peninsula and Oriental Company that a mob of people had refused to allow the mails to be landed in Brindisi. A telegram was sent out immediately ordering the vessel to proceed to Trieste, and land the mails there. With regard to the next steamer, which would bring a much heavier mail, his opinion was that it would be better to order the steamer to proceed by sea direct to England, and instructions would be given to that effect.

Lord **FOLKESTONE** asked what precautions the Government intended to take against cholera when the vessel arrived in this country.

Mr. **FAWCETT** said he had communicated with the Privy Council on the subject. Every care was taken to disinfect the bags, which were soaked in tar, and the decision of the Sanitay Committee of the Privy Council was that that was sufficient.

CHOLERA AT BOMBAY.

In answer to Mr. O'Donnell, Mr. J. K. **CROSS** said cholera has been little, if at all, more prevalent in Indian ports during the last six months than it usually is. In Calcutta the deaths in April were 459, against 318 in April, 1882; in May they were 383, against 380 in 1882; and in June 150, against 254. The health statement of Indian ports is always telegraphed fortnightly for communication to the Sanitary Boards in the Levant, and the cholera deaths in Bombay are telegraphed weekly to the Consul General at Cairo. Her Majesty's Government have objected to the imposition of special measures of quarantine against arrivals from India with clean bills of health and having no suspicious cases on board after a voyage of ten days.

Correspondence.

INDUSTRIAL ASSURANCES AND SPECULATION IN LIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps no section of the community is so conversant with the amount of speculation by way of insurance as the general medical practitioner. The various ways in which he obtains his knowlege brings him more in contact with this manner of business than the public generally. The striving of the insurers to obtain certificates of death that will not prejudice their interests, their calling in of medical men for no other purpose than to be able to give the certificate of death, although the patient has been attended for months by the parish or infirmary doctor. Their dread of such terms as phthisis, chronic bronchitis, Bright's disease, &c., come before us from the patients' side.

From the other side, the practitioner, especially if he has consented to act for offices who pay him low fees, is often asked *to examine* (!) the proposed person unknown to them, as they know nothing of the affair, and I am sorry that the profession is so crowded that men are found to do this. The medical officer, therefore, unwittingly lends himself to the fraud.

If you, Sir, could lend your powerful influence to putting a stop to this you would, by doing so, confer an unmixed benefit on the public, and would raise the status of the profession to a much greater extent than you will do by doing away with the legitimate employment of the unqualified assistant.

The speculating in life assurance, the dabbling in lottery racing tickets are two evils of the industrial classes that are not outdone even by the drink traffic, yet we have Salvation armies, Blue Ribbon armies, Alliance and total abstinence societies all levied against this *one* evil of drink. Now, Sir, can nothing be done in the two others.

It is only a short time since I had *five* proposals put in my hand to call on the people and examine them. I had previously told the agent I should not call on proposers who did not know a proposal had been made to insure their lives in the office, but on seeing to the *five* cases *four* were entirely ignorant. *One* case was an old pauper and under the parish doctor for two years, this proposal was for £100 which, of course, I could not recommend to the office for acceptance, *two* more shared the same fate. Now, I have acted for this office, which is the only one that pays me a respectable fee for industrial cases, for a number of years, but since this time have not been requested to examine any more for them. I need not say that some time ago I gave up all the *cheap* offices, and have refused to act for others.

A claim against one of these industrial societies has been made recently in the Wigan County Court but decided by the Judge in favour of the insurance company. An Act of Parliament, 14 George 3, chap. 14, "An Act for regulating insurance upon lives, and for prohibiting any such insurances excepting in case where the persons insuring shall have an interest in the life or death of the persons insured." And as the plaintiff had not this insurable interest he was non-suited. It transpired, however, that there were *eight* policies taken out on this man's life for a total of £222 6s. 0d., *six* of these were speculative, being held by persons who had no interest in the life of the insured, but *a lot* in his death.

It is a shame, however, that insurance companies should get off in this manner, for by their agents this speculation is encouraged, lives are proposed, and the proposal, signed very often by the agent himself, in fact, this quiet form of forgery is not considered of any harm, and looked on very often by the agent as part of his business.

If poor people are to lose their money after being *induced* to insure lives by the agents of these companies, it is time the powers that be bestirred themselves.

Apologising for trespassing at such a length on your valuable space,

I remain, yours faithfully,

Wigan, July 7th, 1883. WILLIAM BERRY.

◆

TREATMENT OF FRACTURES OF THE PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is a pity that Mr. Robert Jones, of Liverpool, should attempt to criticise an invention without first making himself master of the subject. One would imagine from his letter to you that I had done him some injury, or quarrelled with him over some point or another. I have never heard of Mr. Robert Jones until I saw his letter to you, therefore I cannot understand why he should make such a violent attack against my invention, mis-state facts, and make me to say that which I have never said. Let Mr. Robert Jones first see, and apply the appliance properly, and read my article over again; he will then be probably aware that he wrote without knowing what he was writing about. Firstly, he states that mine is an "older method" than that of Mr. H. O. Thomas. I inquired of instrument makers and hospitals, but could not see or hear of anything approaching it. As to "movement of the fractured ends," I never said or thought of such a thing. Anyone applying the apparatus will find that in bed it keeps all parts at perfect rest, but that in walking there must be some "slight" movements in the joints (not amounting to flexion and extension), whilst the "fractured ends" are kept at perfect rest. Put a long outside on to a patient, and there will be "slight" movement in the knee-joint if the patient attempts to walk. As to Mr. Thomas's method of treatment, it is my misfortune never to have heard of it before, and consequently I am not in a position to criticise it. Thanking Mr. Robert Jones for his comparison with "the tender mercies of a sea-captain,"

I am, Sir, yours, &c.,

H. PARSON.

◆

A WARNING TO MEDICAL MEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The above is the heading of a pertinent, truthful, timely leader in the last issue of the *Medical Press and Circular*, and with your permission I will occupy a small portion of your space for a week or two to acquaint the profession with some experiences of county court law; as it is intolerable that honest citizens, whose education was duly paid for, who have houses and families to support, whose rents, rates and taxes must be discharged, and whose contributions in cash to national or local calamities are looked for as matters of course—it is intolerable, I say, that those potent officials called county court judges can snub, dodge, persecute or prosecute these unfortunate men to their hearts' content without fear of any rebuke, official or unofficial, press, public, Parliamentary or judicial.

Clause 31 of the Medical Act gives to "every person registered under it" the legal right to "practise," and "to demand and recover in any court of law, with full costs of suit, reasonable charges for professional aid, advice and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients." This on paper is good, sound and perfect law, but in practice it is found to be so much "a mockery, a delusion, and a snare," that scarcely one medical man in a thousand throughout England, Ireland, and Scotland is bold enough to attempt to recover his dues through the aid of the law. The greater number of doctors are more content to let themselves be used, abused, swindled, and robbed by a grateful public than to have the reputation of being "county court doctors," and to run the chances of being laughed at, cross-examined, bullied and abused by ignorant attorneys, and equally ignorant and insolent county court judges who receive ample salaries for dispensing law, and not for making and dispensing laws of their own. In a case of cutting, wounding, burning, drowning, hæmorrhage, parturition, or any of the thousand ills that flesh is heir to, a doctor would be privately and publicly abused if he demanded his fee before he went on his errand of grace and peace. But when the need of his services has passed by, mark the change. It is well expressed in the following couplet:—

> "When the patient was sick the patient most grateful would be,
> When the patient got well the patient disputed the fee."

And no wonder he would dispute it, when for the outlay of a few shillings he can obtain the services of a pettifogging lawyer to appear before "his honour" and trump up a defence, to cross-examine the plaintiff, insolently encouraged by nods, winks, sneers and jeers from fellow-pettifoggers in court, and not improbably encouraged by word and look from "his honour" himself.

I will, however, assume that a medical man has definitely taken a dishonest patient into the county court, as doubtless many of my professional brethren have found this course, however unpleasant, yet absolutely necessary. The plaintiff is sworn, and here follows the process, supposing there is no defence to the suit, as I have noted it for many years:—Clerk or Registrar—"Does A. B. owe you fifty shillings for attendance and medicine?" "He does." "How can he pay?" "A pound a month." "No, he can't pay a pound a month." "He can; his income is from thirty to forty shillings a week." "Well, but he has three or four other tradesmen to pay from judgment summonses; eight shillings a month is all he can pay. Eight shillings a month, the first payment in twenty-eight days." Remonstrance is useless; so plaintiff accepts his judgment for eight shillings a month, and will consider himself lucky if he ever receives a payment.

The present letter being introductory, I will, Sir, conclude it by shifting the ground a little; for if doctors have reason to complain that they cannot get law or justice as plaintiffs, they have an equal right to complain at times as defendants. For the court officials aid "smart" suitors.

A medical friend, who dispenses his own medicines, has a passion for buying excessive quantities of select and dear drugs. Iodide and bromide of potassium he buys in quantities of 28 to 56 lbs., and so with other drugs. Travellers from wholesale druggists make their calls upon him; to those he gives orders, and at times supplements these by orders to the house direct. Some months ago he sent an order thus, and added—"If iodide of potassium is cheap send me 20 or 30 lbs., if dear send me none, as I have plenty in stock for two or three years." The drugs arrived, and were unpacked and put away some three or four days before the invoice reached him. When it came he was surprised to find iodide of potassium charged at 14s. a lb., instead of 8s. 6d. to 10s. This was pretty smart practice, but as the traveller called regularly, and while drinking my friend's wine or spirits talked politics freely and told "good things" of famous M.P.'s, things went smoothly till, without any warning, he was served with a county court summons for more than £20, to appear in court about 70 miles from his residence. My friend sent the druggist's money, and hopes he will not be given the opportunity of talking politics with their traveller until the Tonquin, Madagascar, and Egyptian questions are settled.

I am, Sir, yours respectfully,

L.R.C.P.

8th July, 1883.

◆

University of Edinburgh.—The following is the first list of candidates who have passed the final examination for graduation in medicine. Those marked * have passed with distinction:—

Brown, John Henry.
Carden, George Schuylor.
Drummond, Alexander Peter.
Hill, John Stonely.
* Hunter, William.
Johnson, Samuel.
Lloyd, Henry Sanderson.
* Mackay, George.
Mackenzie, Archibald.
Mackinnon, Frank Irvine.
Munro, Andrew Watson.
Murray, James Adam Johnston.
* Neinwoudt, Gerrit, B.A.
* Paterson, Andrew Melville.
Priestley, Joseph, B.A.
Reid, George More.
Ross, Chisholm.
Rothers, Frank.
Scott, Harry.
Ward, Allan Oyier.
Warner, Edward Henry.
* Younan, Arthur Charles.

Greenhough, Vernon John.
Gutteridge, Matthew Wilkins.
Craig, James.
Aikman, Alfred.
Beily, Edwin.
Baily, Percy J.
Ballantyne, John William.
* Barker, Theodore Hugh.
Barrett, William Henry.
Barron, Hunter J.
Broatch, George Thomas.
Brown, Charles.
Buist, Andrew Crichton.
Caw, James Matthew.
Clark, Michael.
Clemow, A. H. W.
Cobbett, Ch. Newbury.
Cotton, Wm., M.A.
Cumming, William.
Dalziel, Thomas K.
Davies, D. Rees.

Notices to Correspondents.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

Sufferer.—We cannot select a medical adviser for you. The disease is not difficult to cure, and any competent hospital surgeon can deal with it if you have patience and do as you are desired.

Dr. Carter.—Stimulation, under the circumstances, would be productive of little good. The electrical reaction can be obtained only so long as vitality is preserved, and once the muscular tissue is dead there can be no hope entertained of recovery by employment of the agent. The effects of faradisation are frequently beneficial in cases of contraction.

J. S.—The work you mention is out of print, but there are several equally valuable manuals to be obtained. We cannot advise you in respect to the second question you have asked.

Mr. Edwards.—The specimen forwarded is a section taken from an ordinary sebaceous tumour. There are no indications in it of malignant structure.

LOCUM TENENS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—A correspondent writes to a contemporary to inquire whether there is a medical agency in Ireland through which *locum tenens*, assistants, &c., could be secured. As there is no such agency in Ireland, I shall be glad to furnish the names, &c., of several highly qualified gentlemen for such positions, who, while awaiting appointments, are constantly reading in the Library of this College.

Yours, &c.,
G. F. Blake,
Royal College of Surgeons, Dublin, Assist. Librarian R.C.S.
July 4th, 1883.

A. F. K.—The new preparation can be obtained from Messrs. Burroughs, Wellcome, & Co., who will also doubtless be able to supply you with information as to the remedy you require.

R. L.—Convallaria majalis is growing into extensive use, and is strongly recommended in some forms of cardiac deficiency. It seems, however, to be effectual only in cases where the right side of the heart and the pulmonary circulation are affected. It is comparatively of recent introduction as a therapeutic agent.

Mr. Newton (Manchester).—You should consult the report of the Committee on Fever Hospitals.

A Military Physician.—Your letter is unavoidably held over until next week.

MEDICAL ETIQUETTE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—A neighbouring practitioner has visited a case of mine and reversed my diagnosis and treatment in my absence. I would be glad to know if there be any statute of the King and Queen's College of Physicians forbidding this conduct, and if so, if there be any means of enforcing the same. I would add that, as a matter of evidence, there would be no difficulty, as the gentleman has himself admitted all the facts.

Yours, &c.,
Ballingarry, July 3, 1883. T. Esmonde Cahill.

[There is no written law to prevent a practitioner acting in the manner of which our correspondent complains. It has always been considered a gross breach of medical decorum for a practitioner to visit another practitioner's patient unless in consultation, or unless he is assured that the case has been finally taken out of the original medical attendant's hands. It would of course be much worse if he were to make such visit unasked. But there is nothing to prevent a practitioner accepting charge of a patient once the original attendant has been dismissed.—Ed.]

A St. Andrews Graduate has omitted to enclose his card, not necessarily for publication, but as evidence of *bonâ fides*.

A Visitor.—We are neither surprised at your views nor queries after your visit. The "Heart" institution referred to is decidedly a quack hospital, to which no medical man who values his reputation would care to be attached; this reply will probably be a sufficient answer to your other questions.

RECOVERY OF FEES.

W. J. (Beleek) asks: Would you kindly inform me in your next issue if fees for dispensary tickets which have been cancelled by the committee of management are recoverable at Petty Sessions Courts under the Small Debts Act.

[Yes, the fees can be recovered as a *debt* under the Small Debts Act; the magistrates have jurisdiction in any case where the amount is less than £2, and is not owing more than a year. We should, however, recommend our correspondent to process the issuer or recipient of the ticket, or both, at Quarter Sessions.—Ed.]

Dr. D. (Whitwick).—Your letter is crowded out at the last moment by press of matter; it shall appear in our next.

Secret Drinking.—A correspondent asks us if in our experience we have come across many instances of secret drinking among women, and if so, whether we consider the grocer's wine and spirit licence has anything to do with it. To the first query we have no hesitation in saying that much secret drinking prevails, especially among the middle and lower middle strata of society; but we have not in any single instance been able to trace this to the grocer's shop, a wine cellar being at hand without the necessity of sending out of doors. We have heard it authoritatively stated that, through the facilities offered for secret drinking by the grocer's licence, wives order spirits and have them put down in their bills as tea, candles, &c., in order to deceive their husbands, and that had these same women to send to the tavern for it, they would deny themselves rather than risk the exposure. This is just possible, but we have never come across a case of the kind; our own experience tends to the view that if women suffer from drink craving, they will obtain it at all hazards.

Yorkshire.—Yes, the preparation is thoroughly reliable, and we have no doubt you will obtain good results.

The Dalrymple Home.—A drawing-room meeting in connection with this Inebriate home will be held at the residence of the Earl of Shaftesbury on Monday afternoon. Tickets can be obtained by members of the profession on application to Dr. Norman Kerr.

BUTTER AND STEAM FOR THE HALF-DROWNED!

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—You probably remember the collision lately between two ships in the Channel, bound to New Zealand, and the loss of life in consequence. A clergyman friend of some of those lost and saved in the affair told me that one lady saved, and who had tried to save two other young ladies, was in a very prostrate condition, and under medical treatment in consequence. To get the water out of her inside which she had swallowed during immersion, her medical man gave her quantities of butter to swallow, and ordered her to inhale steam vapour after! Do let me know if this is a "grand discovery!" I have heard of half-drowned persons being rolled on a cask, or hung up by the heels to let the "water run out," but I never heard of butter and steam. No doubt the recovery will be the handle for a howling discourse of miraculous recovery.

Yours truly,
London, July 4th, 1883. Doubtful.

◆

Vacancies.

Downpatrick Lunatic Asylum.—Assistant Resident Medical Officer. Salary, £100, with apartments, rations, &c. Election, August 4th. (See Advt.)

Lambeth.—Medical Officer of Health. Salary, £300. Applications to be sent to the Clerk of the Vestry by July 12, latest. Candidates will not be required to devote their whole time to the office.

Manchester.—Resident Assistant Medical Officer to the Workhouse. Salary, £140. Applications to the Clerk of the Guardians by July 18.

Sheffield.—Resident Medical Officer for the Infectious Diseases Hospital. Salary, £200, with board, &c. Applications to the Town Clerk before July 17.

Stockton-on-Tees Hospital.—House Surgeon (non-resident). Salary, £200. Applications to the Secretary by July 14.

Strabane Union, Strabane Dispensary.—Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, July 18.

Appointments.

Dunn, T., M.B. & C.M., Assistant Medical Officer to the Barony Parish Hospital, Glasgow.

Fear, W., M.R.C.S., Medical Officer for the Horsmonden District of the Tonbridge Union.

Frazer, W., M.D., an Hon. Physician to St. Mary's Home for Invalid Ladies, Bournemouth.

Hamilton, A. A., M.B. Dub., Medical Officer for the Epworth District of the Thorne Union.

Haultain, F. W. N., M.B., C.M., House Surgeon to the Royal Maternity Hospital, Edinburgh

Hewetson, H. B., M.R.C.S., Surgeon to the Eye and Ear Department of the General Infirmary, Leeds.

Lawford, J. B., M.R.C.S., L.R.C.P. Lond., Registrar and Chloroformist to the Evelina Hospital for Children.

Taylor, H. E., M.R.C.S., Assistant Surgeon to the Eye and Ear Hospital, Bradford, Yorks.

Whittingdale, J. F. S., M.B. Camb., House Surgeon to the Royal Maternity Hospital, Edinburgh.

Births.

Seaman.—July 5, at 22 Ledbury Road, W., the wife of W. C. Seamar, M.D., late Surgeon-Major 72nd (Duke of Albany's Own Highlanders), of a son.

Wade.—July 3, at the County Asylum, Wells, Somerset, the wife of A. Law Wade, M.D., Medical Superintendent, of a son.

Marriages.

Clarke—Taylor.—July 5, at St. Stephen's, East Twickenham, Ernest Clarke, M.B., B.S., of Blackheath, to Kate Litton, second daughter of John Hirst Taylor, Esq., of Cambridge Park, Twickenham.

Deaths.

Cupiss.—June 30, Francis P. Cupiss, M.R.C.S., of St. Servan, France, aged 56.

Edmundson.—July 3, at Enniscorthy, Joseph Edmundson, Resident Medical Superintendent of the Wexford District Lunatic Asylum.

Fitzgerald.—June 29, at 5 Duncairn Terrace, Bray, Co. Wicklow, Robert Fitzgerald, M.D., late of Limerick.

Harwood.—May 4, at Sydney, New South Wales, Thomas Soutter Harwood, surgeon, formerly of London, aged 72.

Jewesbury.—July 3, at St. Ives, Cornwall, Charles Frederick Jewesbury, M.R.C.S., L.R.C.P. (late of Ceylon), aged 33.

NOTES ON THE HISTORY OF EPIDEMICS OF CHOLERA.

Compiled by Surgeon-General C. A. GORDON, M.D., C.B.,
Honorary Physician to Her Majesty the Queen.

ANCIENT Hindoo medical writers described cholera under the names *Bishoocheekă* and *Jevarantishar*.

In 1629 it prevailed at Batavia, but information is not available as to whether on that occasion the disease arose locally or was imported.

In Tanjore and Madura it was known as the *mort de chien* in the beginning of the eighteenth century. It made its appearance again with General Pierce's force on the march from Bengal to Masulipatam in 1767-8.

In 1781 it travelled eastward from Ganjam to Calcutta and Sylhet, continuing to recur on the coast of Coromandel from time to time between that year and 1782. In the latter year the disease prevailed at Trincomalee. In 1783 it extended over Burmah and India. In 1816 cholera attacked the forces under the Marquis of Hastings operating in Central India. In 1817 it occurred in Bengal, but did not extend beyond that province.

In 1818 cholera travelled from Bengal to Madras along the coast line, and also through the Central provinces. In the Bombay Presidency the progress of the epidemic was steadily from east to west. In Bengal it progressed upwards along the Ganges and Jumna towards Agra, Delhi, and Hurdwar, meeting in its progress a stream of the same disease travelling downwards from the latter place. On the same occasion the disease extended eastward to Burmah and Malacca.

In 1819 to Penang, Sumatra, Ceylon, Mauritius, and Bourbon.

In 1820 to Tonquin and China.

In 1821 to Muscat; also to the Indian Archipelago.

In 1822 to Persia, having, it was believed, been introduced in Taurus from three different directions—namely, from Teheran on the east, Ispahan on the south, and Bagdad on the west. From Taurus it extended to Tiflis, and thence to Astrakan, where, on this occasion, its progress in that direction ceased. It was, however, conveyed to Aleppo by means of caravans.

In 1823 it recurred in the greater number of places it had visited the previous year; it spread along the shores of the Mediterranean and Caspian Seas, disappearing, not to recur during the five succeeding years.

In 1826 cholera occurred at various places in Bengal, principally at military stations; it extended in turn from Dinapore to Benares, Cawnpore, Delhi, and Muttra. On this occasion it prevailed simultaneously at Benares and Baroda.

In 1827 it raged in Chinese Tartary and in the Delta of the Ganges. It extended on the one hand to Chittagong, Arracan, and Moulmein; on the other to the districts of Agra, Delhi, Nusseerabad, and the Punjab.

In 1828 the latter places were revisited by the disease. But the epidemic extended far beyond them towards the north-west.

In 1829 the current, extending as just stated, reached Herat, Bokhara, Teheran, and Khorassan.

In 1830, Astrakan, which had suffered during the previous year, was again attacked, so also was Neuberg.

In 1831 the epidemic extended to Bulgaria, Galicia, Berlin, Paris, Vienna, Warsaw, St. Petersburgh, Archangel, Sweden, and England, overspreading also the intermediate territories.

In 1832 it reached Montreal from Dublin. It appeared in New York and Philadelphia, and spread over the whole of the United States. It extended upwards along the St. Lawrence, reaching Detroit and Amherstburgh. It also extended downward along the course of the Mississippi. It prevailed in Spain and Portugal, in Madras and Central provinces of India, but only slightly in Bengal proper.

In 1833 it reached the United States by a different route from what it did in the previous year, but was conveyed northward along the same route as on that occasion.

In 1834 cholera had all but disappeared in Europe. In India it prevailed at Sylhet and Cachar, at Dinapore, in the Central provinces, and along the valley of the Nerbuddah; also in the Bombay presidency.

In 1835 it was at a low ebb throughout Bengal. In the south of France it prevailed with great violence, especially at Marseilles and Toulon, extending also to Italy, where it languished during the winter.

In 1836 at Milan; along the Dalmatian coast; at Ancona and in Sicily. In India there was little of it except at Ghazepore, where the British regiment occupying that station suffered severely.

In 1837 the scourge left Europe for a time. Rome was the last city attacked before the epidemic disappeared. It had visited in the course of the year Marseilles, Berlin, Prague; in England, Coventry, and the *Dreadnought* hulk moored off Greenwich; it attacked Malta and Gozo. It occurred in ports along the Somali coast, having been carried to them, it was believed, from Malabar; from them it extended to Zanzibar. In India, at Dinapore and Cawnpore; in Lower Bengal. It also prevailed in Central Asia.

In 1838, throughout the Bengal presidency; in the North-Western provinces, extending thence towards Cabul.

In 1839 it reached that city; it appeared at Quettah in August, and during the year prevailed at almost every station in Bengal.

In 1840 the Punjab and Central India were absolutely free from cholera. The disease prevailed in Lower Bengal and in Catack. It was believed to have been conveyed to the Straits and to China from Calcutta by means of the troops forming the expedition which then sailed.

In 1841 it recurred in the districts in Lower Bengal attacked by it the previous year.

In 1842 it prevailed throughout Lower Bengal, but did not extend upwards beyond that province.

In 1843 it was very severe at Agra.

From 1840 to 1843 it attacked the Straits Settlements; the whole seaboard of China, from the North of Burmah downward along the Irrawaddy to Rangoon; to Moulmein; another current of the epidemic travelling through Chinese Tartary, and so on to Cabul.

In 1844 one current of the disease travelled westward from Bokhara, visiting Yarkand and Kokan to the north-east of Persia. Another current progressed from the Punjab eastward to Delhi. In Bengal proper only a few stations were visited by it.

In 1845 cholera extended to the south and to the west from Peshawur; to Jhelum, Hyderabad in Scinde, and to Kurrachee; by a second current to Loodianah, Umballah, and Meerut; by a third to Teheran, Tartary, and Derbent, on the Caspian; it also raged in Ceylon. Thus the epidemic extended to Persia and Arabia from two sources—namely, Central Asia on the north, and Bombay on the south.

In 1846 cholera prevailed over the Bombay presidency. It was also at Aden, Mocha, along the greater part of the seaboard of the Arabian peninsula. It spread upwards along the Tigris and Euphrates to Orfa. On the other hand, it extended to Zanzibar.

In 1847 it was again at Derbent. It spread to Tenirkhan, Astrakan, along the coast of the Black Sea to Trebizond, to Novgorod to the north, and Moscow to the west.

In 1848 the epidemic reached India from Central Asia, to which, as already observed, it had in 1840 to 1843 extended from China. It prevailed at Calcutta, Dinapore, and Cawnpore, but did not extend upwards beyond Agra. It occurred at Decca and Pooree. A current extended westward through Arabia, Poland, and Sweden. It visited Egypt and Russia. It was introduced into New York and New Orleans by emigrants from Havre; and from New Orleans spread upwards along the Mississippi.

In 1849 it extended over Canada, reaching the Dominion, not from the eastward, as in 1832, but from the United States. Early in the same year a few cases occurred in Austria, Vienna, and Gibraltar; the disease extended southward in France to Marseilles, and thence to Toulon, Nice, Genoa, Naples, and Brindisi. Paris was also attacked, and the greater part of England visited by the epidemic. In Asia, Behar and Central India suffered, and the disease reached Bombay from the east.

In 1851 it was virulent in Egypt; also along the African side of the Mediterranean; slighter over the greater part of Europe and America. It spread over Mexico and California, Cuba, and Jamaica. It prevailed in the south-western parts of Bengal, in Bombay and Madras presidencies, and along the western seaboard of India. It ravaged Poland, the western provinces of Russia, and along the left bank of the Vistula to Prussia. It occurred in the south of Persia. From Bussorah it spread along two routes—namely, west to Hillah, and east to Mohamerah.

In 1852 it extended *via* Astrakan to Russia; southwards along the borders of the Caspian Sea into Trans-Caucasia. In India it prevailed over the north-western provinces; it extended to Ghurwal and Komaon; at Simla, Almorah, and in the Punjab.

In 1853 the epidemic was in the north of Persia; it travelled *viâ* Bassorah to Bagdad, and extended over Mesopotamia. It occurred in Russia, Denmark, and Sweden; in England; in Bessarabia and neighbouring States; in Piedmont; in Barbary; in Portugal and France; in Prussia; in all the West India islands; in New York and New Orleans. It prevailed also in Dacca and Assam; it extended upwards to Cawnpore, but there its progress ceased.

It 1854 it prevailed throughout nearly every country in the New and Old World. In the Bengal presidency its occurrence was limited. It was conveyed to the Mauritius.

In 1855 it prevailed over all Europe, a considerable part of America, and the West Indies. The troops in the Crimea suffered severely by the disease. It prevailed in Asia Minor, in France, and in Great Britain. It occurred at various places in Persia and Arabia; also in Behar, Gorruckpore, and on the Nepaul frontier.

In 1856 the epidemic was at Recht, the capital of the province of Ghilan on the Caspian Sea; at Teheran and other places in Persia. It occurred in several places around Agra; from there it spread to Gwalior in the south, Nynee Tal in the north, Lahore and Ajmere in the west. At the same time it extended to the Central provinces; to the presidencies of Bombay and Madras. It occurred at Meean Meer with severity in the month of August. It prevailed at the hill stations on the Simla range of the Himalayas.

In 1857 it showed itself in the north-east of Persia; it spread to Shiraz, where it prevailed with great violence. It occurred among the forces around Delhi, and among those in sickness.

In 1858, at Teheran and Mohamera. At Mecca, and at many places along the Arabian coast of the Red Sea. It occurred with violence at Aden, Berbera, and Lahedje, extending also to Zanzibar and Mozambique.

It is observed that during the three years including 1856, '57, and '58, the disease had nearly ceased in a great part of Europe and America.

In 1859 cholera reappeared suddenly at several places in the United Kingdom; in London and Hull; at Wick in Caithness-shire, prevailing in the latter place with unusual severity. It recurred at Mecca. It extended through Lower Bengal, and up to, but not beyond, Cawnpore. It prevailed at Bombay and along the great tract of India from Kurrachee to Cape Comorin.

In 1860 it prevailed over Persia; in Bengal, Oude, and Bombay; it extended from Assam to Darjeeling, and was very intense at Agra.

In 1861 it continued with severity in Persia. It prevailed over the whole of Bengal proper; it was at Allahabad, Gwalior, Jubbulpore, Agra, Muttra, Umballah, and most intensely at Meean Meer. It is stated with regard to the progress of the epidemic in Northern India that no particular circumstance seemed to affect its course; it crossed, and moved directly contrary to currents of rivers and of the wind; that when the winds blew in directions favourable to the course of aerial miasmata the epidemic did not appear to advance with any particular velocity; that it spread from particular points in all directions independently of all known conditions.

In 1862 a severe cholera epidemic occurred in Pekin; on that occasion it first appeared at Taku, then at Tientsin. It also prevailed at Shanghai, and at Canton in the south of the empire.

In 1863 cholera extended upwards along the valley of the Ganges; it stretched on one side to Hazarabagh, on the other to Oude. The epidemic visited Bombay also, being, it was said, conveyed thither by means of pilgrims.

In 1864 it prevailed over Bengal, Central and Western India, and in Bombay.

In 1865 along the Malabar coast; in Mysore, and at Bellary. In Bombay and Scinde; along the shores of the Persian Gulf; in Yemen and the Somali country. It reached Mokalla and Mocha; it spread to Aden and to Abyssinia. It prevailed in Egypt; it spread to the Mediterranean ports, and from thence inland everywhere. It affected Bagdad, Odessa, and Constantinople. From Odessa it spread to Saxony and Germany; to Italy, France, and Spain. It extended from the East into Portugal and Malta. From Bordeaux it was conveyed to New York. India, Bengal, and the Punjab were comparatively free from it.

In 1866 the course of the disease extended to St. Petersburg. It included Bavaria, Saxony, Belgium, Holland, the north-east of France, and, in fact, the greater part of Europe. The epidemic again occurred at Mecca. It spread into Mesopotamia, through Kurdistan and Persia. It prevailed in the west of India; in the Punjab, Cashmere, and Affghanistan. It occurred in Italy; in Great Britain; in Dublin; in Holland. It reached New York from England and elsewhere. From New York it radiated in various directions. In India its prevalence was on the increase in Bengal proper and in Behar; also throughout the North-Western provinces.

In 1867 it prevailed in the Punjab, Cashmere, and Affghanistan. It existed in some parts of Europe, including Galatia, Switzerland, Sardinia, &c. It was present in Russia. It declined over the continent of America generally; it spread, however, in the Argentine Republic, and in towns situated on the banks of the La Plata. From the north of India it spread to Persia.

In 1868 it spread from Abyssinia into Central and Southern Africa; to Zanzibar; and for the first time appeared on the West Coast, breaking out at the Gambia, and thence extending downwards along the coast line.

It is said generally that from 1865 to 1868 the direction followed by the disease in Persia was from west to east.

In 1869 the epidemic reached Zanzibar from the interior of Africa. It prevailed in Central India and in Persia. It crossed the Turkish frontier into the district of Khalis. It appeared at Kiev, and thence spread into the surrounding districts. It was also at Reshed on the Caspian; at Bakir and at Astrabad. The epidemic travelled from Bengal north-west to Cabul, south to Cape Comorin, south-east to China, and west through Africa. From Kiev it spread north-east to Moscow, and from Nijni Novgorod down the Dnieper to Odessa. From Moscow, north-west to St. Petersburgh; and thence, south-west to Warsaw.

In 1870 it extended from Persia, *via* Russia to Western Europe. It prevailed in Central Asia, extending in such a manner from different points that difficulty exists in tracing its precise lines of progress.

In 1871 it broke out in Asia Minor. It prevailed in Constantinople. From Russia it extended to Finland. It existed in Affghanistan and the Balkhan. It spread to Persia and Arabia. India was tolerably free from it.

In 1872 cholera appeared at Jozakh in Turkestan. It spread with great rapidity to Samarkand, Hissar, and Amu Darya on the south; to Bokhara and Kokan. It visited Kiva and Taskent, branching thence towards Lake Issky, and on the other hand to the Russian fort No. 1. Thus its progress in all was in three several directions—namely, south, west, and north. During the same year it visited Vienna and other parts of Austro-Hungary; also Roumania, Prussia, and Belgium.

In 1873 it prevailed in Munich; also in Prussia, and along the valley of the Vistula. In Europe generally, however, the epidemic began to subside. It prevailed in New Orleans and along the valley of the Mississippi. Its progress throughout the United States was said to be in all directions—viz., north, south, east, and west, according as the pressure of commerce, travel, or war propelled it.

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL.

By ALFRED BARING GARROD, M.D.,
F.R.C.P., F.R.S., &c.,
Consulting Physician to King's College Hospital, London.

Lecture III.

(Concluded from page 24.)

Influence of Hippuric and Benzoic Acids.—How is it that the urine of the sucking calf contains a notable quantity of uric acid, seeing that the same animal, when it grows up and takes its ordinary food, excretes an urine which is devoid of this principle? Why should the simple alteration of food cause such a result if uric acid is formed in the kidneys themselves? Is not this fact completely opposed to the second view? Before endeavouring to explain these difficulties, I thought it desirable to prove the fact, and examined first the urine of two sucking calves. In both I found distinct evidence of the presence of uric acid. At the same time, I discovered another previously unknown fact—viz., that the cow's urine, also under certain circumstances, contains uric acid, as when taking turnips, mangold, brewers' grains, and such like food, with little hay or grass, and that, with such a diet, there is little hippuric acid in it. In the horse's urine, which was rich in hippuric acid, I found no uric acid.

At first sight it would appear to follow from these various facts, that the seat of origin of uric acid is further back than the kidneys, and that these organs merely eliminate it from the circulating fluid; in other words, that what we have called the first view is the correct one; but I have already shown, in my first lecture, that the kidneys will not act as filterers of uric acid, even when that principle is known to exist in the blood. Still, difficulties remain against those who advocate the second view, and, until these be cleared away, I cannot feel that this latter has been placed on a satisfactory basis.

Some little time ago, in thinking over the subject of gravel and calculus, I arrived at the idea that, if the urine of man could be maintained in a condition resembling that of the herbivorous mammal, there would be no such things as uric concretions, uric gravel and calculus would be unknown. While following up my idea of assimilating the urine of man to that of the herbivorous mammal, I made these experiments.

I took a specimen of healthy human urine, of full specific gravity, and sufficiently rich in urates to give a free deposit of uric acid crystals when acidulated With this I filled two tubes to about one-fourth of their capacity. To the first of these I added the urine of a horse, so as almost to fill the tube; to the second I added the same quantity of distilled water, in order that the amount of dilution of the human urine should be the same in each tube. After the tubes had been kept for some two or three hours at about 100° Fahr., their contents were examined. A few drops of hydrochloric acid added to the second tube—where water had been used as the diluent—caused a slow crystallisation of uric acid, but the acidification of the first, in which the urine had been diluted with that of the horse, failed to exhibit any precipitation; nor, when it was evaporated to a small bulk, could uric acid be detected either by the murexide or any other test. The experiment was repeated with the substitution of the urine of the lion for that of the horse. This failed to cause the disappearance of the uric acid.

If these observations are correct, we have arrived at a remarkable conclusion, for we have found, not only that the horse's urine is itself free from uric acid, but that it possesses the power of destroying, at least to some extent, the uric acid contained in the urine of man. It struck me that this conclusion was one which might be fraught with weighty consequences, and deserved, or rather demanded, much further and stricter investigation to corroborate it. Such proof, you will find, is not wanting.

I next took eight very small uric acid calculi, none of them larger than a pin's head, and, by the aid of a solution of carbonate of lithium, dissolved them in a little water. To this solution, I added about eight ounces of the urine of the horse. After the mixed fluids had been kept some few hours at the temperature of the body, no uric acid could be detected.

This experiment shows that uric acid, in the form of calculi, when first dissolved in an alkaline solution, is destroyed by the influence of some ingredient which is present in the urine of the horse. After reflecting upon these phenomena, I endeavoured to find out what was the principle contained in these urines of the herbivora which imparted to them this peculiar power; and, seeing that they are rich in hippuric acid—a substance absent from the urine of the carnivora—I instituted a very numerous set of experiments upon the action of this acid on uric acid.

First, a strong solution of hippurate of potassium was mixed in equal quantities with a cold solution of the urate of the same metal, and kept for some few hours at the temperature of the body. On subsequent examination for uric acid by the microscopic test, none could be found nor could any be detected by the murexide test. Another recorded observation is as follows. A cold concentrated solution of urate of ammonia was mixed with a strong solution of hippurate of sodium, and slightly alkaline with the carbonate; after being kept for a few hours at 100° Fahr., no uric acid could be found.

As it might be urged that the uric acid, though existing, was masked by the presence of other matters, the following observations were made, and have been frequently repeated. A cold solution of urate of ammonium was added to one of hippurate of sodium, and the solution made slightly alkaline with the carbonate, so as to imitate as nearly as possible the conditions which exist in the urine of the herbivora. On immediately placing a drop on a microscopic slide, and acidulating it with hydrochloric acid, numerous long crystals of uric acid were soon formed, and afterwards rhombic crystals of uric acid were seen, these latter being readily distinguished by their characteristic shape, and by their intense polarising power for light. After about half an hour, the solution having been previously warmed up to the temperature of the body, a second drop was examined, and the uric acid crystals were found to be much less numerous, and, in another hour or so, they were not to be detected at all. The solution was afterwards evaporated, and no evidence of uric acid could be discovered either by the microscope or the murexide test. The appearances are shown in Figs. 1 and 2. By this observation the fact that a change slowly takes place in the solution of the mixed salts is demonstrated; and it is also proved that the uric acid is not simply masked by the presence of other salts, for it is readily exhibited when the solutions are first mixed, and only slowly disappears under the influence of time and warmth.

In the earlier experiments which I made, which were qualitative only, it was found essential that the hippuric acid should be in large excess, in order that the results should be conclusive; but I was soon led to make quantitative experiments, so numerous that their enumeration would be tedious. I shall, therefore, only give you the results obtained and leave the details to be studied elsewhere, if desired.

In these observations I have used the urates of ammonium, sodium, potassium, and lithium, and acted upon them with the hippurates of the same basis, and I have uniformly found that when hippurates and urates are together in solution a change ensues, the urate becoming gradually destroyed, and probably a part of the hippurate also. It has required, under the conditions which have been present in most of the experiments, nearly fifty times as much hippurate as urate for the complete destruction of the urate; but, when the dilution was much increased, the quantity of hippurate required seem to be lessened, as little as twenty-five parts of hippurate being sufficient. Possibly in the animal body the action takes place more rapidly than in the flasks of the laboratory. The details of my experiments are contained in the appendix to a paper recently read to the Royal Society.

It is generally supposed that hippuric acid replaces uric acid, that is, is formed in its stead in the system. It does indeed replace it, though not, as is usually thought, by being formed, under certain circumstances, instead of it, but on account of its possessing the power of removing the uric acid after it has been produced in the renal cells. The explanation holds good equally with reference to the occasional presence of uric acid in the urine of the adult herbivorous mammal. Under their ordinary diet a certain amount of uric acid is also present in large quantities, some times as much as 1—1·5 per cent., in which case no uric acid can be discovered in the urine; but, when these animals are made to eat food which fails to yield hippuric acid, the uric acid remains intact, and hence it is that, from time to time, we hear of the presence of this principle in the urine of herbivorous mammals.

Now it follows necessarily that what happens in the case of these lower animals, applies also to man. If the quantity of hippuric acid becomes increased, the uric acid becomes diminished, and we are in a position to explain an observation made by Heller, who, in conjunction with a friend, first ascertained the quantity of uric acid which each excreted daily when under an ordinary diet; they then changed the character of their food—Heller living for a week on wheaten and rye bread—his friend on rye bread only, water being the sole drink of both. The uric acid soon began to diminish and to be replaced by hippuric acid, and, at the end of a week, a mere trace of uric acid was found in Heller's urine—none in that of his friend. During the next week, on an ordinary diet, the hippuric acid gradually diminished and the uric acid reappeared in the former quantities. Doubtless the character of the food, in these experiments, had a direct influence on the formation as well as on the destruction of the uric acid, for the amount of the nitrogenised elements of the food must have been small.

We know that glycine or glycocol (gelatine sugar), which enters into the composition of the bile of many animals is closely connected with hippuric acid, that this latter can be broken up into benzoic acid and glycine, when boiled with caustic alkali, and, in fact, benzoic acid, when absorbed from the stomach, takes up glycine and becomes converted in the system into hippuric acid and is thus thrown out in the urine. Such being the case, I thought it most desirable to try the influence of this body upon uric acid and to find out whether it plays any part in the change of the uric acid. I made numerous experiments, using glycine in place of hippuric acid, the other conditions remaining the same, and in no instance did I observe any change in the uric acid; even when days or weeks had elapsed. I then had to look to benzoic acid and ascertain whether the change in the uric acid was due to its influence, and for this purpose I completed a set of observations corresponding to those previously made with hippuric acid. The results were as follows:—

I found that benzoic acid, in the form of a benzoate, when in contact with an urate in an alkaline solution, caused the same slow change in the uric acid which ensued when a hippurate was employed. This change, however, cannot be well observed under the microscope because the crystallisation of the benzoic acid is so rapid that the presence of uric acid is obscured; but, when the solution is evaporated and the benzoic acid removed by alcohol, the murexide test can be readily employed. In the appendix to my recent communication to the Royal Society, I have detailed the various observations on this point, which appear to show that about the same amount of a benzoate as of a hippurate is required fully to effect the change in the uric acid.

If hippuric and benzoic acids in an alkaline solution possess the power of changing and removing uric acid, it is natural to suppose that, when the blood is in an abnormal state from its presence, the administration of the salts of these acids should prove valuable; for there is no doubt that, if hippurate of sodium be added to a blood-serum which show the presence of an urate, the latter is soon removed from it. Clinically, I have derived great advantage from the administration of these salts, which I have used very largely in cases of gout; and patients have asked to be allowed to continue taking them, so much did they think they were benefited by them. To us at the present time, it is important to ascertain whether they are of value in cases where uric acid is liable to be deposited in any portion of the urinary tract. This I shall endeavour to do.

In the first place, these salts act advantageously on the mucous membrane of the bladder and its appendages; and, in cases where there is a disposition in the urine to become ammoniacal from decomposition, they are most useful in checking such tendency. This action on the membrane may influence much the secretion of the colloid matter, and thus prove valuable in cases of gravel and calculus, which are so intimately associated with its urine; and lastly, it may have an effect upon the excretion of uric acid—a point which I must endeavour to ascertain.

I have said that the usual absence of uric acid from the urine of the herbivorous mammal is due, not to its non-formation, in small quantities, in their kidneys, but to the presence of considerable quantities of hippuric acid in the urine; and that, provided that we remove this latter principle by an alteration in the food, assimilating it to that of the young sucking animal which takes milk only; or by giving vegetables which do not yield hippuric acid; that then uric acid appears in the urine. Ought we not, therefore, to conclude that the administration of benzoic or hippuric acid would influence the excretion of uric acid? Is this the case? In the herbivora, the urine is always alkaline in reaction; in man it is acid. In my experiments on the destructive influence of hippuric or benzoic acid upon uric acid, I found it important to use solutions made alkaline with a carbonate, thus imitating, as nearly as possible, the condition of herbivorous urines.

I will here give you the results which I have obtained.

First Set.

The average of four days' urine passed at 12 noon; breakfast at 9 a.m.; specific gravity 1015; diet normal.

5 fluid ounces gave of uric acid 0·63 grains.

After benzoate had been taken 34 hours, and 95 grains taken in repeated doses.

5 fluid ounces gave of uric acid 0·126 grains.

After omitting benzoate 76 hours.

5 fluid ounces gave of uric acid 0·665 grains.

So that, in these experiments, the uric acid appeared to be much diminished by the influence of the benzoate.

Second Set.

Urine at 11 p.m.; dinner at 7 p.m.; no drug taken.

5 fluid ounces gave of uric acid 0·34 grains.

Urine at 11 p.m., after 55 grains of benzoate administered in divided doses.

5 fluid ounces gave of uric acid 0·03 grain.

So that, as far as these experiments go, the uric acid was reduced to one-tenth of its original amount by the action of the benzoate.

Third Set.

Benzoate of soda in 30-grain doses, three times a day. Urine from 11 a.m. to 11 p.m., after having taken benzoate for 12 hours.

Total quantity = 39 fluid ounces.

Uric acid in the 12 hours = 3·90 grains.

Urine before taking benzoate, from 11 a.m. to 11 p.m.

Quantity = 31 fluid ounces. Uric acid = 4·96 grains.

So that the quantity of uric acid was much diminished by the benzoate.

Fourth Set.

Benzoate of soda given in 20-grain doses, three times a day. Urine passed from 11 a.m. to 2 p.m., after 60 grains had been taken. Quantity 5¾ fluid ounces; specific gravity 1020; evaporated to 5 fluid ounces.

Total uric acid = 0·17 grain.

Urine passed from 11 a.m. to 2 p.m., after 120 grains of benzoate had been taken. Quantity = 9½ fluid ounces; specific gravity 1016; evaporated to 5 fluid ounces.

Total uric acid = 0·57 grain.

When no benzoate had been taken for 27 hours. Urine from 11 a.m. to 2 p.m. Quantity = 8 fluid ounces; specific gravity 1018; evaporated to 5 fluid ounces.

Total uric acid = 1·00 grain.

When no benzoate had been taken for 51 hours. Urine from 11 a.m. to 2 p.m. Quantity = 12 fluid ounces; evaporated to 5 fluid ounces.

Total uric acid = 1·25 grain.

When no benzoate had been taken for 75 hours. Urine from 11 a.m. to 2 p.m. Quantity = 10 fluid ounces; evaporated to 5 fluid ounces.

Total uric acid = 1 grain.

In this last set of experiments, during the administration of the benzoate, the uric acid was diminished in a remarkable degree.

The results of the preceding observations made with the alkaline benzoates differ from those obtained by myself in 1842, and also from those of Kerner, in 1858, on which occasions benzoic acid itself was employed. Nor is it difficult to explain the discrepancy, for we know that benzoic acid, given by itself, increases the acidity of the urine, as is well shown when it is administered in cases of phosphatic urine; and, under these circumstances, it can possess little or no power of changing any urate it may meet with in the renal cells or other parts of the urinary tract. I am still engaged in clinically investigating the value of the benzoates and hippurates, both in cases of gout, and of gravel and calculus; and I hope ere long to bring the further results before the profession. I can confidently affirm that I have already obtained great advantage in the treatment of these diseases from their employment.

I frequently give the benzoic acid in the form of benzoate of sodium; but, if I wish at the same time to increase the quantity of the urinary excretion, then I give the benzoate of potassium or of lithium; and, if there be an abnormal acidity of the urine, some alkaline citrate.

Seeing that herbivorous animals excrete hippuric acid in a greater or lesser quantity according to the character of the food upon which they are fed, I cannot help thinking that some article of diet might be devised for those who suffer from the diseases above mentioned, which might, at least to a great extent, keep in check the tendency to form and deposit uric acid.

We are asked to announce that H.R.H. the Duke and Duchess of Connaught will visit Norwich on Monday, August 20th, for the purpose of inaugurating the new hospital buildings in that city. A fancy bazaar in aid of the hospital will be held on that occasion.

MINERAL WATER INHALATION.

By W. G. BLACK, F.R.C.S.E.

Having visited Bournemouth lately, I took the opportunity of going over the grounds and foundations of the new Mont Dore establishment being erected there for the cure of complaints by the inhalation of mineral waters. As it is a novel form of treatment in this country, according to the scheme sketched out in the prospectus issued, it should meet with favourable opinion, and as the origination of a new and practical form of treatment for pulmonic affections, it should have hopeful augury of success.

The system is already adopted in some Spas abroad, and notably at Mont Dore in France, from which the scheme takes its name, and which popular resort I visited a few years since, and saw the recognised mode of pneumatic treatment by inhalation of vapours. It should be pointed out that the mineral waters there are *naturally hot*, and therefore easily vaporised in the closed chambers, while the waters at Bournemouth must be *artificially heated*, which will necessitate more expense in fuel than required at Mont Dore. The system usually employed is that the mineral vapour introduced into *large rooms*, with cemented walls and stone floors, and the windows and *doors are closed* for the short period of inhalation required by the patients sitting inside them. The vaporisation of the mineral water is chiefly effected by spray machines, so that the temperature of the inhaled mixture of air and water is kept at a moderate degree, and within physiological limits for absorption by lungs and skin. The invalids at their hotels dress themselves in flannels, and are carried in closed sedan chairs to the inhalation chamber, where they sit down on the benches or chairs to inspire the vapour, or walk about to and fro on the floor. After a quarter of an hour's treatment the chamber *is opened*, and the patients return to their sedan chairs and go to their hotels to rest, and redress themselves, and are prepared in time to take their *déjeuner*, or late breakfast, about 11 o'clock. The like treatment could be carried on at our own British mineral spas, which are supplied by hot natural waters, as those of Bath and Buxton, easily.

There may be seen at some of our Spas *vapour baths* for the use of the invalids, but these are found to be supplied only with pipe or common fresh water. It may seem curious that the *natural mineral* water itself had not been used, as it was handy, inexpensive, and pure, and already warmed by Nature.

The objections urged by people maintaining the present methods with plain water, are that the mineral waters would be spoiled by boiling, and no medicinal ingredients would be distilled off in the vapour. But this is now obviated by the *vaporisation* being effected by the spray machine, along with air, or steam, as the motive power of the blast, and the temperature of the effective vapour need not necessarily be at an uncomfortable height for sustaining its maintenance and respirability along with common air.

Both Bath and Buxton waters contain ample gaseous ingredients, as nitrogen and carbonic acid, being suitable for medicinal inhalation, but their saline and earthy constituents can also easily be made respirable by the agency of spray vaporisers, disseminating them in the air. Though vapour inhalation is most adaptable by using *naturally hot waters*, yet it is just as likely that success might attend the utilising of such *cold mineral* waters as those of Harrogate, especially as they contain a vaporisible gas, the sulphurreted hydrogen. The vaporisation of the *sulphurous* ingredients from these waters could be easily effected by spray machines, without injuring them by previous artificially heating, and it would probably minimise the unpleasant odour of the waters, if they were combined with steam. The remarkable immunity from bronchitis and pneumonia enjoyed by passengers and seamen on board ship, when exposed to inclement weather, would cherish the belief that the artificial vaporisation of *sea water* might lead to equally good results when applied to the cure of diseases of the chest, in patients frequenting our health resorts. On the other side of the question again, there are aqueous sprays or watery mists charged with poisonous ingredients, deleterious to the health of the lungs and air passages, known commonly as London or city fogs.

It has been alleged by some investigators of the action of inhalation of medicated vapours (not including gases) that but infinitesimal quantities have been found to be really absorbed into the lungs or blood by the mechanical processes they adopted. Attention, however, may be drawn to the difference existing between inhalation by an instrument, as an ether inhaler fitted to the mouth, whereby the lungs only are influenced, and the general inhalation practised in a large chamber full of vapour. In this case, the whole superfices of the skin are brought into the sphere of operation of the vapour, as well as the lungs, just as takes place in the natural experiment in sea air or city fog, the effects of which no one can hesitate to accept as being very appreciable. As to the mode of action of the skin then, it may as yet be a matter for conjecture, whether it be an absorbing agent or an emunctorial one, or whether it assists the lungs or the lungs assist it in absorption of vapours, will remain to be determined by experimental investigation.

Clinical Records.

LOUTH COUNTY INFIRMARY.

Cases of Compound Fracture – Tetanus – Recovery.

Under the care of Dr. HERCULES MacDONNELL.

Patrick Garland, æt. 27, was admitted to the County Louth Infirmary on October 11th, 1882, suffering from a compound comminuted fracture of the right foot. While assisting at a threshing mill, his right foot was caught in the machinery, and the entire fore part pulverised.

With difficulty a sufficiently large flap was obtained, and a modified Chopart performed. The operation was performed under strict Listerian precautions. The dressing was removed in two days, when the wound looked healthy in every particular. Evening temp. 98·4.

Oct. 18th.—Dressed antiseptically. Morning temp. normal; evening 99.

19th, 20th, 21st, 22nd.—Temp. normal. Sleeping well.

24th.—Slight stiffness in jaw. Stump dressed. Looking healthy.

25th.—Tetanic symptoms more marked. Dressings removed, and linseed poultice applied. Ordered a mixture containing in each dose 12 grs. of chloral and 10 grs. bromide of potass every five hours. Temp. normal from this date.

26th.—Opisthotonos well marked. To have one oz. ol. ricini.

27th.—Bowels moved once. Taking 2½ quarts of milk daily.

28th.—Spasms more frequent. Abdominal muscles retracted and rigid. To have chloral and bromide mixture every second hour; 3 oz. brandy, and 1 oz. Liebig's extract in a pint of beef-tea daily; milk ad libitum, to be used warm.

29th, 30th.—Spasms increasing in frequency and length. Hot stupes to epigastrium.

31st.—Urine retained; drawn off every eight hours by catheter. Bowels confined. 1 oz. ol. ricini; ½ oz. ol. terebinth.

Nov. 1st.—Bowels moved three times. No sleep. Twitching of both legs constant. Spasms every five minutes.

2nd, 3rd.—No sleep. Spasms almost continuous. To have oil and turpentine again.

4th.—Bowels moved once. Motion, tarry. A slight trace of pus on the poultices. In one of the spasms a portion of one of the pectoral muscles was ruptured. Relieved by strapping. Sleeping a little at intervals.

5th.—Diminution in frequency of spasms.

6th.—Got some sleep last night. Tongue thickly coated.

7th.—Jaws not so stiff. Spasms still diminishing in frequency and severity. To have oil and turpentine again.

8th.—Spasms involving larynx more than previously. To have 16 grs. of chloral and 12 grs. bromide every second hour instead of previous mixture.

9th, 10th, 11th.—Opisthotonos less marked. Spasms diminishing steadily.

12th, 13th, 14th, 15th.—Improving daily. Only six spasms on 15th. Discontinued poultices. Stump dressed with tenax, oil and turpentine again, as bowels are confined.

16th.—Slept fairly well. Bowels moved three times, of a natural colour. To have a mixture containing bismuth and gentian; at night a draught containing 30 grs. of chloral. Perspiring freely. Abdomen still rigid.

17th.—Spasms have ceased entirely. To have rice for dinner.

21st.—Has been improving rapidly. Sleeps fairly well. Moved into another ward, and is able to sit up.

Dec. 3rd.—Was up and dressed to-day. Stump completely healed.

Case II.—John Duffy, æt. 9, admitted to the County Louth Infirmary on May 27th, 1879. A wheelbarrow passed over his hand, and crushed the nail and top of the third finger of the left hand on May 13th.

May 27th.—Tetanic symptoms appeared this morning, the jaws being stiff and muscles of back arching. Risus sardonicus fairly marked. To have a jalap and calomel aperient; also a mixture every fourth hour containing 5 grs. each of chloral and bromide of potass. The extensor tendons do not act.

28th.—Bowels not moved. To have 3 drs. of ol. terebinth, and half-an-ounce of ol. ricini. Pulse 100. Evening temp. 100.

29th, 30th.—Jaws very stiff. Abdominal muscles rigid. Eyes peering.

31st.—Two good motions yesterday. Spasms affecting larynx slightly.

June 1st.—Better this morning. Spasms lighter and less frequent. Had some sleep last night.

2nd.—Jaws not so stiff. To stop chloral and bromide mixture.

10th.—No stiffness in jaws now, but a copious acniform eruption came out. To have a mixture of quinine and iron.

18th.—Eruption has gone almost completely. Left hospital to-day.

Remarks.—In Case I. the tetanic symptoms did not appear for twelve days, began then to increase in severity, and did not diminish for twelve days more. During these twenty-four days the patient took 6 oz. 6 drs. of chloral hydrate, and 5½ ozs. of bromide of potass. The combination of these drugs seemed to exercise a marked influence. On several occasions I purposely exhibited only one of them for a couple of doses consecutively, and its influence seemed very much impaired. The use of turpentine in connection with castor oil has a most beneficial action, changing completely the character of the stools, and unloading the colon, the first action of the bowels being tarry, and the second much better in colour and consistence, owing, I believe, to the direct action on the intestinal mucous membrane. The temperature in both these cases was only slightly and temporarily elevated. As far as my experience goes of seven cases of acute traumatic tetanus, unless the chloral and bromide is pushed till the toxic effects are distinctly marked, very slight improvement takes place. The difficulty is to find out the maximum dose the patient can bear.

Department of Lunacy.

THE LINCOLN LUNATIC HOSPITAL.

The Lincoln Lunatic Hospital, which is under the medical superintendence of Dr. Russell, affords excellent accommodation for insane patients of the lower middle classes at very moderate rates of board. A few patients are received at fourteen shillings a week, and a large number at a guinea a week, while the highest charge is three guineas a week. The Commissioners on Lunacy speak very favourably of the condition of the hospital, and of the comfort of its inmates, and of the care bestowed on their amusement and occupation.

THE WEST RIDING ASYLUM.

The West Riding Asylum at Wakefield continues to thrive under the careful superintendence of Dr. Herbert Major, and dispenses much benefit in the district to which it belongs; 428 patients were admitted into it during 1882, and 167 were discharged recovered, while 110 were discharged in some measure relieved. The daily average number of patients resident in the asylum was 1,402, and the total number under care during the year was 1,880. One case of suicide is reported. The occurrence took place in the shoemaker's shop, where the patient had been employed for some weeks, apparently with benefit, and it indicates very forcibly the risks inseparably connected with the employment of patients in many occupations, risks, however, which must be held to be fully justified, even at the expense of occasional disasters, in consideration of the great good which employment confers upon the large number of patients who can be brought under its influence. At the inquest on the case, no blame was attributed to any-one, it being considered that the patient had been justifiably employed as he was when the fatal impulse overcame him. One admirable feature of the West Riding Asylum has been the comparative fulness of its medical staff. Dr. Major makes a complimentary reference to the three assistant medical officers and four clinical assistants who have been associated with him in 1882.

THE WILTS COUNTY ASYLUM.

Mr. Ireland Bowes, the medical superintendent of the Wilts County Asylum at Devizes, gives a very clear and exhaustive account of the hospital under his charge, in his recently published annual report. 737 patients were under care during 1882, 124 were admitted, 35 were discharged recovered, and 65 died. Some cases of diarrhœa which were supposed to be due to atmospheric changes, and an epidemic of typhoid fever visited the asylum, and in connection with this fact the Commissioners in Lunacy observe that the sewers external to the building seem to be imperfectly ventilated, and that the main cesspool is unnecessarily large. They suggest that in order effectually to guard against the admission of sewage gas to the wards the drains where they pass beneath the building shall be constructed of cast-iron tubes with gas-tight joints. During 13 months elapsing between the visits of the Commissioners, 19 men and 31 women were secluded on 42 and 108 occasions respectively, and for a total of 234 and 521 hours. There are still many box beds in the asylum. Wet packing has been introduced quite recently, and 11 patients have been subjected to this restraint for 96 hours. No patient is continuously packed for more than an hour and a half, at the end of which time he is unpacked and examined by the doctor. The result of this treatment is alleged to have been satisfactory. Mr. Bowes gives a brief *resumé* of the lesions found on post-mortem examination in each case of death in his asylum.

THE SURREY COUNTY LUNATIC ASYLUM AT WOKING.

In opening their last report on the condition of this asylum, the Visiting Commissioners in Lunacy refer to the retirement of Dr. Brushfield from the office of Medical Superintendent, and pay a well-deserved compliment to him for the manner in which he had filled that position for many years. The high reputation which the asylum now enjoys they ascribe in great measure to his able and enlightened management, and to the judicious system of treatment which he established. A retiring pension of £700 per annum was granted to Dr. Brushfield, and Dr. Barton who had been previously Senior Assistant Medical Officer was elected to succeed him. Under Dr. Barton's guidance the asylum continues to prosper. The rate of recovery last year amounted to 42·7 per cent. on the number of patients admitted, which is much above the average of British asylums, and the death-rate fell to 6·8 of the average number of patients daily resident, which is much below the average of British asylums. No fatal casualty occurred, but one determined attempt at suicide is reported by a female who inflicted a serious wound on her throat with a broken hair-pin. Dr. Barton is energetic in promoting the employment and amusement of his patients, and justly attributes to them a highly curative and sedative value. He refers to an attempt to provide out-door occupation for women. Sixty female patients were sent into the fields during hay-making and harvesting last summer and autumn. Although they did not do much work they benefited by the novel occupation in the open air.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

Hypogastric Lithotomy.—M. St. Germain, of the Hôpital des Enfants Malades, has just published a very interesting case of hypogastric lithotomy practised on a child eight years old. The patient for three or four years previous had been suffering more or less from those symptoms which generally characterise the presence of a calculus in the urinary receptacle. Examined at the hospital, all doubts on the nature of the case were immediately cleared up, the sound rendering a click when brought in contact with the foreign body. M. St. Germain having selected the hypogastric region for the extraction of the stone, a bag of india-rubber was introduced into the rectum and filled with water in order to make the bladder bulge forward by its distension. The bladder itself was filled with a three per cent. solution of boric acid. An incision about two inches in length was made in the median line of the abdominal wall over the globular tumour constituted by the distended bladder, and this latter being reached, it was incised for a similar length, and the calculus was extracted by means of a long forceps with the greatest facility. Both wounds were united in their whole length with the exception of one point, through which passed a large drainage tube. In spite of these precautions the urine flowed through the wound and retarded its occlusion. However, by degrees the process of cicatrisation advanced, and in three months afterwards, when the patient left the hospital, there remained but a pinhole fistula. It should be stated that the cause of his leaving the hospital was the precarious state of his health, the result of long confinement. This case is no doubt interesting in one sense, as, if I do not make a mistake, it is the first case of hypogastric lithotomy practised on a child; but it cannot be denied that the length of time found necessary for the occlusion of the wound could not have been of advantage to the patient, since his general health became seriously compromised from the long sojourn in the hospital. This new method of operating for stone is gaining partisans on the Continent, but it must be admitted that medical men are not so enthusiastic as to its merits as at first, for they have recognised that the operation is far from being attended with inconveniences—inconveniences which are sometimes serious enough, even in the cases considered the most suitable, to determine the surgeon to abandon it. I have myself witnessed two cases of suspubean lithotomy, or rather one, for the other had to be abandoned almost at the commencement, and the results were not at all encouraging. In the first case the patient died, but hardly as the result of the operation, as he was a very unfit subject for any operation. At the autopsy it was found that the mucous membrane of the rectum was torn in several places in a longitudinal direction by the forced dilatation of the india-rubber bag. In the second case the bag, according as it was filled with water, was expelled by the contractions of the rectum; and when at last the resistance was overcome, it slipped up right into the sigmoid flexure, where it could be plainly felt and seen through the abdominal wall. Thinking it was the bladder, which had been previously injected, as in the first case, the surgeon was going to cut down on it, when some one mildly suggested that it might be the bag. Here, also, as the same amount of liquid was injected for the distension of the apparatus, the rectum, if not the intestine, must have suffered from the same lesions as in the first case. It is, however, no doubt possible that the inconveniences attending the preliminary steps of the operation could be minimised: the india-rubber bag need not be so much distended, and a means might be discovered to hinder it from slipping up. But there exists another inconvenience, which is constant, and that is, not only the length of time necessary for the complete cure, but the assiduous attention required during the whole period. In perineal lithotomy the after-treatment is generally of the simplest kind. In fact, after the first couple of days, the patient is independent of further medical care. Not so in the case of hypogastric lithotomy, for here the surgeon has to be indefatigable in his attention: the wound has to be dressed twice a day, the bladder washed out with an antiseptic solution, the temperature taken night and morning, besides many other minor cares which this operation involves. Consequently the best operation for general country practitioners is not the one forming the subject of these observations, as his time would be seriously compromised. However, that fact, if the operation were found necessary, would no doubt have very little weight with medical men, and justly so. There are at least two cases in which hypogastric lithotomy not only might be performed, but might be imperatively required. The first is an abnormally large prostate, and the second a very large calculus. A third, perhaps, might be added, that in which the patient had been previously operated on through the perinæum.

The whole of the last meeting of the Academie de Medecine was taken up with a discussion on the propriety of that learned body taking the initiative in provoking an examination of the present system of disposing of the contents of the cess-pools, with a view to its amendment. The arguments on both sides were warmly sustained, but otherwise devoid of interest. Professor Ball was elected as titular member of the section of medical pathology.

Trichlorophenate of Lime.—A Russian medical journal publishes an account of experiments made by one of its collaborators on the antiseptic properties of trichlorophenate of lime, a mixture of phenic acid and chloride of calcium. From it, it appears that this compound is twenty times stronger as an antiseptic than phenic acid, permanganate of potassa, chloride of calcium, salicylic acid, or boric acid. It is not only disinfectant, but it removes all odours from wounds. It is essentially useful in soft chancre, diphtheria, and other gangrenous affections. Trichlorate of phenol is not only easily and quickly prepared, but its price is also less than that of phenic acid.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

The Bohemian Lying-in Hospital.—The annual report of this renowned institution, drawn up by Prof. v. Weber, and published in the *Allgemeine Wiener Med. Zeitung*, is a most exhaustive one. In this respect it might serve as a model for similar institutions at home; in another respect—viz., as regards success—the story it tells is as encouraging as any can well be. During the year 1882 the confinements in the hospital numbered 2,963. Out of this enormous number of deliveries there were but 7 deaths—0·24 per cent., or 1 in every 423·3 cases. This is what Prof. v. Weber claims as the correct mortality list; but on considering the different items individually it will be seen that, according to the views of some, the figures require a slight adjustment. Thus, 12 women are reported to have died in the hospital, and 7 others died in the Krankenhaus to which they had been transferred, so that, instead of 7, there were 19 deaths; and, as other lying-in hospitals debit themselves with all deaths occurring in the institution, there is no reason why this one should be an exception. The figures given here show how difficult it is to arrive at accurate results either in hospital or out-door practice. They are capable of three different readings—1st. The reading of Prof. v. Weber, according to which all deaths are excluded not directly traceable to child-bearing; 2nd. That of including the deaths of all patients dying *within the lying-in hospital* within a certain period—say, 30 days; 3rd. That in which are included *all deaths* occurring within the above-named period of 30 days. The latter is the mode of reckoning that ought to be adopted, and, according to it, the deaths would be 0·64 per cent., or 1 in 156. According to the mode of reckoning that seems to be in vogue with us, the number of deaths would be put down as 12—0·4 per cent., or 1 in 247. Whatever mode of reckoning be adopted, the figures are very satisfactory, and an immense advance on those of the ten years 1865 to 1874, during which the average mortality was 6·67 per cent. The writer claims that the average mortality during the last four years—1879 to 1882—has been 0·32 per cent.

The German Hygienic Exhibition.—This exhibition, at once the pride and the astonishment of all good Germans, is now the leading feature in the busy metropolis on the Spree. It must be understood that the exhibition is a German one. It is not a universal exhibition such as we have been accustomed to in England, but as an exclusively German institution, smacks of that exclusiveness and pettiness always inseparable from mere local affairs. Perhaps a great nation ought to consider any national exhibition beneath it that does not accept the best of their kind in the way of exhibits, whatever their source may be. If the sources whence exhibits are to be accepted are to be limited to this or that locality, this or that country or group of countries, the best may be excluded. The aim of excellence or perfection is lost in the infinitely lesser one of locality or nationality. Taken for what it is, however, the exhibition must be acknowledged to be a success and an honour to the German-speaking people. Perhaps no better idea of the scope and subjects embraced in the terms hygiene and life-saving can be given than in an enumeration of some of the articles or appliances for which the Empress Augusta's special gold medals have been awarded. These medals, of which there were forty, have been awarded to those contributors who, by their exhibits, have forwarded most effectually the general designs of the exhibition. The first was awarded to Dr. Josef v. Fodor, Buda Pesth (scientific apparatus for determining the carbonic acid in the atmosphere, carbonic oxyde in the blood; for demonstrating the properties of the soil, and for hygienic works and Kartogrammes). 2. Dr. Georg Recknagel, Professor and Rector of the Royal School of Industry, Kaiserslautern (group of exhibits comprising differential manometer, pocket anemometer, thermotelegraph, hydrotelegraph, lactodensimeter, &c.). 3. Der Berliner Volksküchen Verein (workman's eating establishment) in full work. 4. Dr. Hermann Cohn (graphic representation of the increase of shortsightedness in German Gymnasien). 7 Badischer Frauenverein, Karlsruhe (the sick institutions of the ArchDuchy of Baden, the nursing duties of which are performed by the members of the Baden Ladies' Society). 11. P. Dörffel, Court optician and mechanician (complete ophthalmic clinic). 12. Schimmel and Co., Leipzig (antiseptic preparations, chemical products, ethereal oils, &c.). 14. Bairischer Verein for the care of the wounded and sick on the field, and Bairischer Frauenverein, Munich (land transport wagons for wounded, literature, &c.). 15. Central Comité of the Netherland Red Cross Verein, the Hague (stretchers, messengers, dressings, ambulances). 21. Agricultural machine and implement and wagon. Building company (machines for street-sweeping and cleaning snow-plough, spring wagons, food transport wagons). 22. Siegmar, Elster (gas meters, apparatus for analysis of gas, for lighting railway carriages, gas heating apparatus, safety lamps). It will be seen from the above examples that hygiene and life-saving can be made to cover a very wide field. One of the most interesting parts of the exhibition is that occupied by the German Imperial Health Office, which, of late, has exercised such an important influence over medical thought everywhere. We hope to give our readers a short account of this department, and of its working, at an early date.

◆

THE MEDICAL ACT AMENDMENT BILL AND THE SCOTCH EXTRA-MURAL SCHOOLS.

A joint meeting of Edinburgh and Glasgow extra-mural lecturers was held, on Thursday last, at the Royal College of Physicians, Edinburgh, for the purpose of considering the provisions of the Medical Act Amendment Bill. There were upwards of thirty gentlemen present, about half of whom were from Glasgow. Dr. Littlejohn, Medical Officer of Health for the City of Edinburgh, who was called to the chair, said he regarded the Bill as a most important one, affecting as it did not only the personal position of the extra-mural lecturers, but the still greater subject of medical teaching in Scotland. So far as Scotland was concerned, the Bill was essentially a University measure, and while they willingly allowed that they shared in the prosperity of the Universities, they at the same time believed that they contributed to that prosperity, and that if the extra-mural schools of Glasgow and Edinburgh were destroyed, the Universities would sooner or later sustain serious damage.

Dr. Morton, Glasgow, in moving the first resolution—"That, in the opinion of this meeting, the position and interests of the extra-mural medical schools of Scotland were entirely overlooked by the late Royal Commission, and have been equally ignored by the Government in framing the Medical Act Amendment Bill now in the House of Commons"—said he thought they ought now unitedly to push forward their case, and he submitted the resolution in the full confidence that those who professed to aim at purity of examination and freedom from monopoly in teaching would support them. It seemed to be somewhat singular that a Bill professing to aim at these two points should still seek to retain in the power of the Universities the right to grant licences of all kinds with the exception of an additional licence which the Government intended to grant.

Dr. Stevenson Macadam, of the Edinburgh School of Medicine, in seconding the motion, said that the Bill was clearly one-sided. In England and Ireland justice had been done to the universities and corporations alike, but so far as Scotland was concerned it was a university and a non-corporation Bill, and was likely, if passed, to do serious harm to the extra-mural teachers. He thought that the Government, before framing so important a Bill, should have made full inquiry in regard to the medical schools in Scotland as well as in England and Ireland. Dr. Macadam also referred to the Universities Bill, and said that about one-half of the sum of £40,000 which it proposed should be handed over to the universities of Scotland might be fairly considered as belonging to the medical departments, but not one farthing of that was proposed to be given towards the extra-mural teaching of students. The resolution was unanimously adopted.

Dr. Angus Macdonald, Edinburgh, moved the second resolution :—

"That, should the bill pass in its present form, the universities of Scotland, while retaining intact their monopoly in granting degrees, will, by their enormous majority on the Board, become also possessed of all examining and licensing power, and thus in Scotland will be the absolute masters of the portals of the profession, and that, in the opinion of this meeting, a monopoly so complete will lead not only to destruction of the extra-mural schools, but in the end will prove disastrous to the universities themselves and to the cause of medical education in Scotland."

He said that if, as had been proposed, the corporations held only three votes on the Board, they would really have no voice whatever, and those who leaned upon these corporations for the maintenance of their interests would, whenever their interests clashed with those of the universities, find themselves entirely out in the cold. Charges had been made as to the laxity which existed in the examinations by the corporations in Scotland, but he held there was no real warrant for anything in the shape of penal action being taken with regard to the corporations from any proved laxity.

Dr. Clark, of Glasgow, in seconding the resolution, said he was convinced that the Bill was essentially a good Bill, and that the passing of a measure on the same lines, but not exactly in the same form would be highly beneficial to extra-mural tuition. One essential point in such a Bill was that they should not be handicapped by the great preponderance in the Board which was given to the universities under the present scheme.

Dr. Wolfe, of Glasgow, proposed an addition to the resolution, but it was held to be incompetent at that stage, and the resolution was then adopted.

Dr. Ebenezer Duncan, of Glasgow, proposed the third resolution :—

"That this meeting desires to impress upon the Government the fact that the origin and progress of extra-mural teaching in Scotland has been chiefly owing to its free and full recognition by the corporations, and that there being no present arrangements under the Bill whereby the extra-mural teachers can be directly represented on the proposed Medical Board for Scotland, the meeting is of opinion that each of the Scotch corporations should return at least two representatives to the Board, in order that the interests of the extra-mural schools may be preserved."

They believed that the Scottish corporations were to a large extent representative of the profession in Scotland, and consequently ought to have a large share in the composition of the proposed Board. The proportion which the Government proposed to give to these corporations was, in view of the interest which they had at stake in medical matters, absurdly small, and would really give them no influence whatever.

The resolution, after having been seconded by Dr. Craig, Edinburgh, was agreed to.

Dr. Wolfe then submitted as a separate resolution that which he had proposed to be added to the second resolution, and which had for its object the desirable condition that teachers should not occupy the post of examiners of their students. This, however, was negatived, as it was thought that the Government had heard enough on this subject.

On the motion of Dr. C. Muirhead, of Edinburgh, seconded, by Dr. Patterson, of Glasgow, it was agreed that the resolutions adopted should be embodied in a minute of the meeting and forwarded to the Government. The proceedings then terminated.

The members afterwards dined together.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

Subscriptions for France are received by Messrs. Bailliere, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

Subscriptions for Russia are received by Messrs. Rajchman and Frendler, 18 Senatoren Street, Warsaw—post free £1 5s. 0d. per annum.

Subscriptions for the United States are received in New York by Messrs. Willmer and Rogers; Philadelphia, by Dr. Brinton: post free in advance, 5¾ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 18, 1883.

THE MEDICAL BILL.

The announcement by Mr. Gladstone that the Government proposes to pass the Medical Bill in preference to many other important measures which it has been found necessary to drop will be received with satisfaction and relief of mind by medical reformers. It would be truly unfortunate if a Bill which had such a groundwork of inquiry and consideration, and which has been accepted by the profession without serious cavil, should come to nothing, and leave the subject to be re-opened and the agitation for reform renewed for years to come. We earnestly trust that Mr. Mundella will adhere to his determination to carry the measure through, and that he will see his way to smooth its path through the lower House by granting reasonable amendments.

In our opinion, the chief fault of the Bill is that it in some measure sacrifices the medical corporations to propitiate the universities, and that it does this without any demerit on the part of the corporations or any special right of the universities to have a predominance. Mr. Mundella seems to be impressed with the belief that university medical education and examination is something much higher and better than collegiate education and examination. There may be ground for this notion in the case of universities which insist upon their *alumni* being cultured in arts as well as medicine ;

but in the case of other universities which are merely examining centres, there is not the slightest ground for according to them a larger influence on the medical system of the future than is given to the colleges.

Acting under the influence of this delusion, the Bill has been made to suit the Scotch universities especially, and—to please them—an opening has been designedly left for the Scotch medical boards to take up a lower educational standard than the other boards, and thus to continue the existing system of under-selling England and Ireland. The Bill provides that the examination level shall be uniform throughout the Kingdom, but, by omitting to provide for the same equality of curriculum, it clearly implies that the medical boards may please themselves in this respect, and that it is not the function of the Medical Council to adjust the three medical board schemes to an even level. Now, as long as two forms of proof of the competency of the practitioner—*i.e.*, examination and course of study—are recognised by the Bill, it is plainly illogical and unjust to provide for a minimum standard of the examination proof and to leave the education proof to the caprice of the medical boards. It certainly cannot be tolerated that the Scotch board shall bid down for the patronage of the student by lowering its educational standard, and the Bill will not be acceptable until this defect is remedied.

◆

VOLUNTEER MEDICAL ORGANISATION.

SOME few months ago a movement was set on foot, by the exertions of Surgeon-Major Evatt of the Army Medical Department, to organise among the medical students of London a volunteer corps of surgeons trained for the performance of active duty in the field. The scheme received at first but a limited amount of attention, but through incessant activity on the part of its advocates it is now becoming much more generally and enthusiastically supported; and several hospital corps have been formed as a result of Dr. Evatt's determined prosecution of his plan for creating a large and useful auxiliary force to the existing medical departments.

The method pursued in this connection is to bring together for purposes of drill as many students at a school as are willing to engage in the work. These are then put through a regular course of instruction—first of all in the ordinary company drill in which every soldier must be made proficient, and subsequently in the special evolutions connected with ambulance work. In this latter relation, as bearers themselves, every student so instructed is made acquainted with the actual details of such mechanical duties as are regularly performed by the bearer companies of army corps, and is thereby, through the only experience that can be of any permanent value to him, placed in a position of ability to direct such bearers aright should he ever be called on to superintend their labours when on active duty. That these exercises, moreover, are useful in many ways apart from the experience they confer can hardly be doubted; and the best proof of this is to be found in the gratifying success attending the movement already. At the outset of Dr. Evatt's attempt it was objected that medical students would not consent to undergo the drudgery inseparable from a course of training like that proposed by the scheme. The answer to this is simple and conclusive. Already, at Charing Cross Hospital, over seventy students have completed drills to render them efficient; and at the London Hospital a class of sixty-six is undergoing the necessary instruction; while at St. Bartholomew's Hospital as many more have been for some time in regular practice to the same end. This, moreover, is but a beginning; and it may safely be predicted that ere another year has passed at least every metropolitan hospital will number an ambulance corps among its local institutions.

The technical portion of the instruction these students undergo is naturally so intimately associated with their hospital work that, once the manual labour has been effectively gone through, there is little fear of their failing to deserve confidence as field surgeons; and it is almost incredible that so simple a means of aiding the education of those who design to enter the services in a medical capacity has not long ago been availed of. Dr. Evatt has pointed out with much truth that one of the most serious obstacles to efficient work on the part of army surgeons is their absolute ignorance of the manual details of their profession, and the difficulties they encounter from having never been subject to any disciplinary exercises fitting them for the *régime* of their new existence. It may also be advanced as a prime argument in favour of the ambulance classes, that they necessitate a discipline among their members which is likely to be of invaluable assistance to them in whatever path their future life may lie; while to all who may in any way be required to exercise command it will confer untold advantages by virtue of the superiority which invariably attaches to an officer who has himself excelled in the performances he is directing on the part of others.

The question has already arisen—and as the number of classes and members increases it will attain greater importance—as to the position that shall be occupied in the future by the officers who are turned out as a result of the new movement. Dr. Evatt's own suggestion is to constitute them a special department of the volunteer service, duly recognised by the State, and subsidised by it. That, in other words, a Volunteer Medical Department, equivalent to, and the auxiliary of, the Army Medical Department, shall be formally created, the ranks of which shall henceforth be recruited from the various hospital corps. Each student who has completed the necessary drills, and acquitted himself satisfactorily, would then, on obtaining his qualification as a practitioner, become also an officer of the Volunteer Medical Department, and his services would be at all times available when occasion for their exercise should arise. The existence of such a force in times of emergency would be an incalculable boon, and even at the present time how valuable it might prove as a source of volunteer *trained* surgeons for duty in Egypt, is easily seen. Though it would probably be the case that the majority of these men would be tied by circumstances of practice, &c., to a particular spot, yet there would doubtless be always a certain proportion available for even foreign service if the need should arise; and as the numbers holding commissions increased, so would the proportion of aspirants for duty grow also.

It is most desirable that the new movement shall receive support and assistance from the considerable and important body of existing volunteer surgeons; and these last will naturally supply staff-surgeons, attached, of course, to the regiments with which they are now connected, under a scheme of organisation such as Dr. Evatt is suggesting. It need not be again pointed out that complete union of all surgeons trained to field duty, and not permanently attached to the army, will result from the adoption of the scheme in its entirety: this, of itself, will be an immense gain to the profession, which is strengthened by whatever effects a combination of its scattered elements for a common purpose. The advantage to the country of a reliable corps of medical men willing and able to assume the care of wounded in the field, trained in habits of discipline, and competent to direct the labours of others with a view to saving life and retarding suffering—this needs no further enforcing. The numerous benefits associated with the scheme, indeed, are so many and manifest that it is impossible to be other than satisfied with the progress it is making, and to hope and anticipate for it a speedy and ample recognition on the part of those "in authority."

◆

A SURGICAL KNIGHTHOOD.

Her Majesty's advisers have condescended, at length, to take cognisance of the fact that the medical profession in Ireland has been for years excluded from participation in the honours which have been liberally dispensed to English and Scotch physicians, and they recommended the Queen to confer on Mr. Porter Her Majesty's surgeon in Ireland the stamp of knighthood. We have, as may be recollected, expressed ourselves warmly respecting the slight put upon Irish physicians and surgeons by refusing to them for so long any public recognition of their place amongst the profession of Great Britian, and we, long since, claimed for Mr. Porter the distinction of baronetcy which has been conferred on English and Scotch surgeons and on Irish surgeons of twenty years ago. We thought, and think so still, that Mr. Porter by his qualifications as a scientific surgeon, the confidence which the public reposes in his skill, his personal and social qualities, the ample independent fortune which he enjoys, and the official position which he occupies as surgeon to Her Majesty, is in every way worthy of as high distinction as has been granted to any English or Scotch surgeon. We insist moreover that the medical profession in Ireland, whether its members be regarded from a scientific, a social, an educational, or an executive standpoint, are entitled to occupy, and do in fact occupy as high a position in public esteem as their brethren either north or south of the Tweed. It is, therefore, with indignation and contempt that the medical profession in Ireland receives Mr. Gladstone's tender of knighthood to Mr. Porter. So far as the offer of such a distinction, honour, decoration, or whatever the Queen's advisers may please to call it, can be considered as a recognition of Mr. Porter's rank and attainments, we congratulate him upon it, but speaking for our profession in Ireland, we emphatically repudiate Mr. Gladstone's condescending patronage, and we have to suggest to Her Majesty's advisers the propriety of reserving their ginger-bread titles for ex-lord mayors, and if they regard the profession in Ireland as not worthy of a gentleman's position we ask that they will be pleased not to seek to lower them before the public eyes by throwing them the scraps from Her Majety's table. The insult to the profession in Ireland which the offer of knighthood implies is enhanced by a retrospect of what has been the usage in times past. It is but a few weeks since that Mr. Spencer Wells as President of the English College of Surgeons was made the worthy recipient of a baronetcy, to-day an ex-president of the Irish College of Surgeons is made to feel that knighthood is good enough for mere Irish doctors. Within Her Majesty's reign the proposal to confer a baronetcy was preceded by its grant to the following English and Scotch physicians and surgeons:—

Sir James Clark, Sir Henry Holland, Sir Charles Locock, Sir William Lawrence, Sir William Fergusson, Sir James Simpson, Sir Thomas Watson, Sir William W. Gull, Sir James Paget, Sir William Jenner, K.C.B., Sir George Burrows, and Sir Robert Christison.

The precedent thus established had been followed in Ireland where Sir Henry Marsh, Sir Philip Crampton, and Sir Dominic Corrigan were given the baronetcy, and we know of no occasion on which this the custom of marking surgical distinction by the higher title has been departed from. Sir William Wilde got knighthood for his work as an Irish Census Commissioner, Sir William McCormac for his able discharge of the General Secretariat of the International Medical Congress, Sir George Owens and Sir William Carroll for having well discharged their functions as Lord Mayor of Dublin, Sir Robert Jackson for long and valuable military services, Sir Erasmus Wilson for his present of Cleopatra's Needle to the nation, and Sir Oscar Clayton for Heaven knows what, but in no single instance, we believe, has any decoration of a lower grade than baronetcy been offered as a recognition of high surgical or medical attainments, and we trust that it has now been offered for the last time.

As to Mr. Porter's personal relation to this unpleasant episode we must do him the justice to state the fact that when the first offer of knighthoood was made to him he explicitly declared in his reply that it was no fitting decoration for the surgeon to the Queen in Ireland and objected to receive it as such, and it was not until he had been officially informed that nothing else would be granted, and after he had taken the advice of members of our profession whom he considered competent to form a judgment on such a subject that he, acting on their advice, expressed himself as willing to take the lesser title. We think that in so doing Mr. Porter and his advisers formed a most unhappy decision, and we are confident that the refusal of this humiliating offer would have raised Mr. Porter in public estimation as much as his acceptance of it will lower him. The opinion of the Irish daily press is unanimously with us on this point, and we can only join with them in hoping that the Queen's advisers will see the diplomatic error they have committed and the injustice they have done Mr. Porter and Irish surgery, and amend it by conferring on him the honour of baronetcy as they would undoubtedly have done if he resided in London or Edinburgh. Should Mr. Gladstone refuse to take this course we can only say that the profession in Ireland expect that Mr. Porter will not humiliate them by taking a lower grade, but will respectfully intimate to the Lord Lieutenant that respect for his profession prevents him receiving the proffered title.

Notes on Current Topics.

Sanitation in Dublin.

At the last meeting of the Dublin Public Health Committee, the Superintendent Medical Officer read a report relative to the existing arrangements for the disinfection of clothing and infected premises; also for the removal of patients suffering from infective diseases to hospital. Plans were laid before the committee of proected alterations at the disinfecting chamber.

A letter was read from the College of Physicians in reply to the resolution of the Public Health Committee, on the subject of the threatened approach of cholera to this country. The college have referred the matter to a committee consisting of the president, vice-president, Dr. Grimshaw, Dr. Finny, the Rev. Dr. Haughton, Dr. Chapman, and the Registrar, who are to meet and draw up a report upon it. In compliance with the request of the North Dublin Union Board of Guardians, the committee appointed the master of the workhouse as a sanitary officer.

Dr. Hunter and the Cholera in Egypt.

The appointment of Surgeon-General Hunter to medical control during the cholera epidemic in Egypt by her Majesty's Government is a happy one in every way so far as the experience and ability of that officer is concerned. As a member of the Indian Medical Service, he has necessarily enjoyed full opportunities of studying cholera, and as formerly in charge of a large civil hospital at Bombay, is well qualified to judge as to the relative merits of the several methods of treatment in that disease which from time to time during the last twenty years have been practised. Dr. Hunter will no doubt be furnished with full instructions as to the precise duties he is expected to perform; suffice it to say for the present, in general terms, that with him will rest "the supervision of the Medical Control." At the same time, a medical man from Italy is about to proceed, or has already started for Alexandria, and M. Pasteur goes as "Delegate" from France.

Doubtless in due time the three countries thus represented will each have the privilege of an elaborate "report." But in the meantime, are we justified in believing that this phalanx of three eminent men is to defy or in any way whatever check the progress or extension of the epidemic now raging until that epidemic has run its own natural course? Unhesitatingly we say—None whatever. Then, again, how far may the Government of the Khedive be expected to give effect to measures proposed by each or all of these delegates, more especially if such recommendations run counter to national habits and belief, or involve the expenditure of money? The information recently telegraphed regarding Mansurah by the correspondent of a daily paper is not calculated to encourage any great hope on either head. But we shall have the inevitable "Report" nevertheless. That will be a gain in itself, even if it be all the result obtained.

But how comes it that the services of the experienced officer of the Army Medical Department who is already in Egypt have not been utilised in devising all measures deemed necessary or practicable on the spot? There is no man better qualified for the task than Surgeon-General Irving; and, moreover, not only was he until lately sanitary officer at Whitehall Yard, but he was also a member of the Army Sanitary Commission. Therefore it was perfectly unnecessary to send to Egypt another officer to do what Dr. Irving could do perfectly well.

The Night Lecture Sham Certificate System in Dublin.

The Council of the Irish College of Surgeons has, we regret to say, decreed free trade in night lecturing. The vote of the Council on this point was led up to by the vote of the College at large, which, as we have already stated, had made up its mind to pretend to a confidence in the *bona fides* of night lecturers, and to appeal to them to desist from the dishonest but lucrative practices which they have pursued for years past. Strange to say, this decision was mainly influenced by a section of the reform party, who argued that, though they knew night lecturing to be a means of evading medical study, and though they were fully aware that the certificates granted in respect of night lectures were to all intents and purposes sham certificates, nevertheless proposed to continue the sham certificate system because it did not seem to them of much importance whether certificates are sham or real. The matter came to a vote in the Council, and, backed by the influence of a College vote, the night lecture party carried the day, but only by the casting vote of Mr. Wheeler, the President, and the refusal to vote by Mr. Macnamara, the representative of the College in the Medical Council. Mr. Macnamara's speech in the Medical Council in defence of night lecturing, and his refusal to vote on this occasion, are eloquent anticipations of what may be expected from the Irish Branch Council when it comes to answer the charges made by Dr. Jacob to the General Medical Council. No one can be better informed as to the *mala fides* of night lectures than the members of the College Council and of the Branch Council; and yet we shall doubtless see the latter attempting, as it did before, to equivocate itself out of the necessity for declaring honestly its opinion respecting this lucrative trade in certificates. But the attitude of timid people has force—in this matter only in the direction of delay. They may stop the reform by a year or two, and so put so much additional money in the pockets of the sham certificate traders, and send out so many additional incompetents into practice; but they cannot make the public or the profession believe that it is right to continue to sell false certificates of study at so much per, nor can they deny that this trade is carried on wholesale by the night lecture party. Things have come very close to a break-up with that party when they can only carry a new lease for their practices by the casting vote of a President, or the tergiversation of a Medical Councillor.

Brigade-Surgeon O'Leary.

What a pity it is that the following copy of a letter, addressed to Dr. O'Leary by Surgeon-Major Ramsay, could not be added to the "Proceedings" of Lord Morley's Committee. At all events, it is right that the friends of Dr. O'Leary should have an opportunity of reading it—namely :—

No. 2 Station Hospital, Curragh Camp,
10th March, 1883.

My dear O'Leary,—I cannot imagine how or from whom General Drury Lowe got the statement that "a batch of thirty or forty men requiring medical aid" was sent away from the field hospital without getting it; but I can assert most positively that no such thing ever happened. As to their being sent away by you, that is too absurd and quite impossible. Had such a thing been done, it *must* have been done by me. I can swear it never was done. How any man with common sense could invent or believe such an impossible absurdity is more than I can imagine. It is utterly untrue from beginning to end.

Thanks, I am now all right, and I think this place will quite set me up. I hope you are fit again, and that you will find Egypt more comfortable than it was when you left it.

Yours sincerely,
(Signed) T. Ramsay.

P.S.—To prevent any possibility of mistake or misconception, I can state most positively that no words such as you are stated to have used have or could have been used to any man or "batch of men" at the field hospital without my knowledge; and further, that, to my knowledge, no such words were ever used to any man or batch of men at the field hospital by you or any one else connected with the hospital.

(Signed) T. Ramsay, Surgeon-Major, A.M.D.

In justice to Dr. O'Leary, we trust that some member of Parliament will take an opportunity to bring to the notice of "the House" the preceding letter, exonerating Dr. O'Leary as it does completely from unfounded allegations made in regard to him. No doubt the general officer concerned will take the earliest practicable opportunity, if indeed he has not done so already, to withdraw, or at any rate *nullify*, impressions made by what turns out to be a statement based upon error or misconception.

"Evolution" of Epidemics.

In a pamphlet on the subject, ("Instances of the Evolution of Epidemics.") Dr. Pearse, of Plymouth, endeavours to indicate the "evolution" of epidemic diseases, also that the process to which he applies that term means no more than that particular conditions of the human body coincide with, or are brought about by physical and other conditions under which an individual or community exists at a particular time. In this sense the term selected is perhaps as good as any other, but means no more that "circumstances alter cases." Among the conditions which affect the state of the system he includes changes of climate incidental to long sea voyages, changes of physical surroundings, changes which accompany the succession of seasons, and so on. Alluding to the occurrence of a case of cholera among a shipload of coolies in the passage from Calcutta to the West Indies, Dr. Pearse asks: "May we assume that the choleraic type evolved from the change to water a somewhat difficult physical state on board ship to which he was habituated in India, just as fatal cholera has often occurred after taking seidlitz or Epsom salts." But, inasmuch as either of the salts mentioned appears to have been in the water on board the *Alnwick Castle*, it follows that the comparison drawn has no reference to similar circumstances or conditions. One point raised by Dr. Pearse is important at the present day when so much is being written on the subject of *entities* in the causation of disease. He does not believe in the existence of a "specific poison of cholera." Nor do we.

The Advance of the Telephone.

The manifold advantages conferred by telephonic communication between hospitals and the residences of members of their staff are too evident to be long unrecognised. For some time now Dr. Clement Godson has been using a telephone, laid from his house to St. Bartholomew's Hospital, and so great a convenience has he found it that strong representations in favour of generally adopting this means of intercommunication have been made to Sir Sydney Waterlow, treasurer of the charity. In response to these appeals, Sir Sydney has sanctioned the employment of the telephone throughout the hospital, and for providing communication between it and the homes of physicians and surgeons to the institution. This step will commend itself to every one as an important advance, and as taking very proper advantage of the facilities afforded by scientific improvements to reduce the labours of heavily-worked members of the profession. By the new arrangement it will be possible, very often, for verbal directions to take the place of actual presence, and thus for a surgeon, for instance, to be saved the labour of journeying in the middle of night, or during the busiest time of day, to the hospital where he may chance to be summoned by the arrival of a serious case. It is to be hoped that the example set at St. Bartholomew's will be generally followed in London.

Mr. Jonathan Hutchinson, F.R.S.

Mr. Jonathan Hutchinson, F.R.S., whose reputation as a surgeon has done much to attract students from all countries to the London Hospital—and whose lectures on "Diseases of the Tongue" are now appearing in our columns—will, at the end of the present month, cease to hold the position of senior surgeon to the institution he has so long been associated with. His retirement is necessitated by the rules under which members of the staff are elected, Mr. Hutchinson's term of office having now expired. At a recent meeting of the hospital committee the high esteem in which Mr. Hutchinson is held at the London was shown by his being unanimously appointed to be Emeritus Professor of Surgery at the hospital; and we are rejoiced to learn that in this capacity Professor Hutchinson will deliver, each session, a course of lectures on surgery, extending over six consecutive weeks.

On Friday afternoon a meeting of past and present students of the hospital was held in the anatomical theatre of the medical school, Mr. Walter Rivington, F.R.C.S., presiding, when it was resolved with enthusiasm to raise some fitting "Hutchinson Testimonial," the exact shape of which, however, being left for further consideration. As showing the keen interest excited in the subject, it may be said that, although but a few hours' notice of the meeting had been given, between sixty and seventy gentlemen responded to the summons, among them being several older and eminent past students of the school. A committee was elected to discuss the best method of carrying out the views of the meeting, and to receive subscriptions, which may be paid either to Dr. Andrew Clark, treasurer, or to any member of the committee, the secretaries of which are Dr. J. A. Williams and Mr. Chas. H. Wade. It is understood that, whatever form the testimonial may take, it will be presented to Mr. Hutchinson at a dinner which will be given in his honour early in the ensuing winter session.

A Result of the C.D. Vote.

According to the *Western Morning News* there were at the time when Mr. Stansfeld's motion was introduced into the House of Commons, 460 women in hospital at Plymouth suffering from venereal disease. Now there are 70; so that 390 infected women have been cast loose on society in a single centre, to constitute a blessing derived at the fatherly hands of Mr. Stansfeld.

International Exhibition at Nice.

The favourite and beautiful town of Nice is to be the scene of an important international exhibition in the coming winter, arrangements being steadily in progress to ensure that the opening ceremony shall take place some time in December. Such an attraction cannot fail to enormously increase the number of the visitors who annually avail themselves of the natural beauties of this delightful health resort, and there can be no doubt the exhibition will in no small degree contribute to their well-being by stimulating progress in sanitation throughout the district of which Nice is the centre. The success of the undertaking, moreover, is assured by the assistance and encouragement afforded by a number of prominent English physicians and scientists, who ask also for co-operation from any who, as engineers, pharmacists, mechanicians, &c., can contribute to make the exhibition either more complete or more representative. In Section II. sanitary appliances, pharmaceutical preparations, medical and surgical instruments, &c., &c., are included; and it may fairly be expected that British firms will be well represented among the exhibitors. The official agents for Great Britain are Messrs. J. M. Johnson & Sons, Limited, 1 Castle Street, Holborn.

Mr. George Fleming, P.R.C.V.S.

The distinguished, thrice-elected, President of the Royal College of Veterinary Surgeons, Mr. George Fleming, LL.D., has received an especial mark of the high esteem in which his services are held, by being appointed to the post of Principal Veterinary Surgeon to the Army. This valuable preferment has been made by H.R.H. the Duke of Cambridge, Field-Marshal Commanding-in-Chief, as a well merited recognition of Mr. Fleming's pre-eminence as a scientific veterinarian; and in this way it will be hailed as a most worthy distinction by all who are familiar with its recipient's sterling contributions to the literature of science. Indirectly, Mr. Fleming has done not a little for regular medicine, and his promotion is a gratifying indication that his merit is fully appreciated by the authorities best able to give it fitting reward.

Royal College of Surgeons of England.

At the annual meeting of the Council of the Royal College of Surgeons of England, held on Thursday last, the newly elected members—Sir William MacCormac and Mr. Sydney Jones—took their seats for the first time, and Mr. John Marshall was unanimously elected President of the College in succession to Sir Spencer Wells, Bart., whose term of office has expired. Mr. Cooper Forster, and Mr. Savory were elected respectively senior and junior Vice-Presidents, and Mr. Lund was chosen Examiner, in place of Mr. T. Holmes, whose seat at the Board became vacant by rotation. At the same meeting a committee was appointed to consider a motion proposed by Mr. Cadge to recognise proxy voting at College elections. The members of the committee are—the President and Vice-Presidents, Sir J. Paget, Sir S. Wells, Prof. Humphry, Prof. Erichsen, and Messrs. Lund, Holmes, and Cadge.

The Formation of Fat from Fat-Acids.

Dr. Immanuel Munk read an interesting paper on the above subject before the Berlin Physiological Society a short time ago, to which we are indebted for some interesting observations. Previous investigations had led the author to conclude that fat-acids play the same part in preventing the destruction of albumen that fat itself does. It was ascertained that dogs fed with flesh and fat preserved their nitrogen and body weight in an exactly similar manner when, in place of fat, for weeks together, only the acids of it were given; that the resorption of fat-acids in the intestinal tract was almost as complete as that of fat itself; that, finally, after feeding with fat-acids exclusively, the fatty substances contained in the chyle from the thoracic duct consisted in only a small part 5·13 per cent.) of free fat-acids, and 6 to 17 times as much neutral fat, and not more soaps than after exclusive albumen feeding. It follows from this, the fat-acids on their way from the intestinal tract to the thoracic duct, undergo a synthetic change to fat, which must—in case the diet is one of fat-acids exclusively—be brought about by the abstraction of the glycocol necessary to the synthesis, from the organism itself. The author has now succeeded in proving the transformation of fat-acids into fat.

A short time ago, Lebedeff, after feeding dogs for some time with linseed oil and mutton fat—fats that are not naturally present in dogs—proved the presence of these fats in the animals experimented on. If the above named synthesis of fat-acids into fats really takes place in the organism, the author concluded that by feeding dogs with the acids of fats heterogeneous to the organism of dogs such feeding would be followed by the deposit of these fats in their bodies—and this actually took place. After the author had learned from an experiment that the combined fat-acids of mutton fat, although only melting at a temperature of about 50°C., were digested in the intestines of the dog to 8090 per cent., he proceeded to experiment further. A medium sized poodle, 13·8 klgr. in weight, was caused to fast for 19 days, after which, his body weight was reduced 32 per cent., he was then fed for 14 days with a little lean flesh and as much fat-acids from mutton fat as he would consume. In this period he consumed 2,850 grms. of fat-acids, and 3,200 grms. of lean meat, and again increased his body weight by about 17 per cent. The animal was then killed, and exhibited on examination, an extraordinary deposit of fat in the subcutaneous connective tissue; on the intestines; in the liver, muscles, &c. The fat thus obtained, which was of an exquisite whiteness, was easily proved to be neutral mutton fat, to the extent of 96 per cent.

The blood withdrawn from the carotid artery before the animal's death contained only 0·12 per cent. of fat, and the whole of the blood contained only 1·15 grms., a proof that the fat thus formed synthetically—like that taken up from ordinary nourishment—does not remain long in the blood, but is quickly withdrawn into the tissues.

Alleged Malpraxis.

A case was called last week, for trial at Limerick, in which a woman named Hayes sought damages from Dr. de Landre, for alleged negligence, as a surgeon.

On the case having been called on, plaintiff's counsel said that the case was one in which medical expert evidence was necessary to prove the plaintiff's case. They had that moment received two telegrams from their medical man, at Tralee, in which he stated that he refused to attend at the hearing, unless he received twenty guineas, and ten guineas per day during the trial. Under these circumstances his client would withdraw the action.

Counsel for Dr. de Landre refused to the withdrawal of the record. The action was a thorough bogus one from the beginning, and a piece of sheer ingratitude against a professional gentleman of the greatest ability, and the highest repute in the city of Limerick, and one that should never have been brought. He would ask his Lordship, under the 35th Section of the Judicature Act to dismiss the action with costs. When his Lordship dismissed the case accordingly with costs against the plaintiff.

Miss Arabella Kenealy, second daughter of the late Dr. Kenealy, was successful last week at the King and Queen's College of Physicians, coming out first in order of merit over the 50 candidates for the diploma, and of whom two were women.

The highest annual death-rates from diseases of the zymotic class in the large towns last week per 1,000 of their population, were from measles 1·7 in Liverpool, and 4·2 in Newcastle-upon-Tyne; from scarlet fever, 1·6 both in Sheffield and in Leeds; from "fever," 1·6 in Portsmouth; and from diarrhœa, 2·0 in Portmouth, and 2·1 both in Nottingham and in Preston. The 22 deaths from diphtheria included 12 in London, 3 in Leeds, and 2 in Edinburgh. Small-pox caused 3 deaths in Birmingham, and one both in London and in Hull, but none elsewhere.

Professor Schuethauer, of Pesth, reports in the *St. Petersburg Med. Woc.* the post-mortem upon a woman, aged seventy, where no spleen was found. The organ had not been destroyed by disease, but had never been present.

The Home Secretary has consented to receive a joint deputation from the Canterbury, Dover, Maidstone, Eltham, Sheerness, and other boards of guardians, and also representatives appointed by the municipal authorities of the various Kentish towns affected by the withdrawal of the operation of the Contagious Diseases Acts.

The following office-bearers have been elected for the ensuing year in the Durham University Medical Graduates' Association:—President: Dr. Philipson. Vice-Presidents: Drs. L. Armstrong and Travers. Secretaries: Drs. Mears and Milson. Council: Drs. Arnison, Bowman, Drummond, Bedford, Fenwick, Fielden, Goldsmith, Morton Porter, Tyson, W. T. Wilson, Gibb, and W. Robinson.

The seventh anniversary of the Sanitary Institute of Great Britain was held on Thursday last, when Professor Humphry, M.D., F.R.S., who presided, referred in the course of his remarks to the cholera in Egypt, and so far as Europe was concerned he expressed more confidence in sanitary precautions and cleanliness than in quarantines or cordons. In the evening the members of the Institute dined together, under the presidency of Dr. Alfred Carpenter.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Brighton 10; Derby, Halifax 13; Bristol 14; Leicester, Bolton 15; Cardiff, Edinburgh, Wolverhampton, Salford, Sunderland, Norwich 16; Hull, Bradford, Nottingham, Plymouth, Birkenhead, Blackburn 17; Portsmouth 18; Manchester, Sheffield, Birmingham, Huddersfield 19; London Oldham 20; Preston 21; Leeds, Newcastle-on-Tyne 22; Liverpool 23; Glasgow 28.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Madras 33, Paris 24, Geneva 19, Brussels 25, Amsterdam 23, Rotterdam 21, The Hague 24, Copenhagen 20, Stockholm 22, Christiania 13, St. Petersburg 30, Berlin 40, Hamburg 26, Dresden 25, Breslau 31, Munich 34, Vienna 26, Prague 39, Buda-Pesth 35, Rome 20, Turin 22, Venice 24, Lisbon 26, New York 25, Brooklyn 18, Philadelphia 22, Baltimore 16.

Dr. Stumpf (*Archiv. f. Klin. Medicin.*) has made some interesting experiments on the influence of certain medicines upon the secretion of milk. Small doses of potassium iodide administered to a goat doubled the fatty matter and increased the sugar in her milk, the albumenoids and salts remaining unchanged. Lead slightly increased total solids and albumenoids, but diminished fatty matter. Morphine produced no perceptible change. Alcohol—whether pure, diluted with water, or in the form of beer—increased sugar and fatty matter, decreasing the specific gravity, and leaving the quantity unaffected.

Scotland.

[From our Northern Correspondents.]

The College of Physicians of Edinburgh and the Membership.—At the late examination for the membership of this College four candidates presented themselves for examination, of whom three failed to satisfy the examiners. We congratulated the College on the step they had taken when they instituted the examination for their membership, and we are glad now to be able to state not only that there is an examination, but that it is conducted in every way to the credit of the College. The diploma will soon be eagerly sought after when it becomes known in the profession that it can be worn with credit and honour by the recipient.

Musselburgh Town Council and their Analyst.—The Musselburgh Town Council, finding that some unpleasant revelations have followed the appointment of Mr. Falconer King as analyst, have tried to get rid of their troublesome Mentor, and for this purpose appealed to the Home Secretary to remove him. The appeal was of course refused, as Mr. King's only fault appeared to be the correctness of his reports. The Town Council have tried their last shaft, and have reduced the salary from £15 to £1 1s. 0d. per annum, to be paid quarterly. We believe that Mr. King intends to try the legality of the Council in reducing his salary, and we wish him all success. The case shows how necessary it is to protect public servants in the execution of their duty from the power of men of the stamp which too frequently composes our Local Authorities.

Aberdeen University Court.—At a special meeting of the University Court last week a petition was presented from Dr. Francis Ogston, sen., in which he formally tendered resignation of the Chair of Medical Jurisprudence. Dr. Ogston urged the acceptance of his resignation on the ground of his advanced age. The petition stated that Dr. Ogston was in his 80th year, that he had taught medical jurisprudence as a lecturer, and as a professor in addition, for a period of 44 years. The members of the Court united in paying a very high compliment to the ability with which their venerable colleague had discharged his duties, and resolved to recommend the Privy Council to grant him a retiring allowance. There are eight candidates for the office, viz.:—Dr. Robert Beveridge, Aberdeen; Dr. Angus Fraser, Aberdeen; Dr. John Urquhart, Aberdeen; Dr. William Garden, Aberdeen; Dr. Simpson, Medical Officer for Aberdeen; Dr. Frank Ogston, Aberdeen, a son of the retired Professor; Dr. Matthew Hay, Assistant to the Professor of Materia Medica, Edinburgh; Dr. Aubrey Husband, Lecturer on Medical Jurisprudence, Edinburgh. The election will take place in August, soon after the meeting of the Privy Council, before the prorogation of Parliament.

Melancholy Death of Dr. Robertson, of the Aberdeen Royal Infirmary.—A feeling of sadness has been evoked in medical circles in Aberdeenshire and Banffshire by the melancholy death of Dr. Edward Wagstaffe Robertson, at the early age of twenty-eight years. Deceased as a student distinguished himself alike in the Arts curriculum and the medical classes. For a year prior to his graduation he was house-physician in the Aberdeen Royal Infirmary, and after he took his degrees (M.B. and C.M.) he was engaged for about eighteen months as house-surgeon and superintendent of the Infirmary at Elgin. Upon the retirement last year of Dr. Rattray from the medical superintendentship of the Aberdeen Royal Infirmary, Dr. Robertson was chosen to fill the vacant place, and he discharged the duties of the office with great assiduity and ability. Indeed, there is no doubt that his extreme attention and anxiety in fulfilling his functions in the hospital have directly resulted in shortening his days. A nervous affection, induced by overwork, rendered rest imperative, and Dr. Robertson went for a couple of months' holiday among his relatives. His health thus considerably improved, and last week he wrote announcing his intention of returning to his duties at the Infirmary last Saturday. That morning he was accidentally drowned in the river Mersey, near Little Sutton. His death is widely regretted, and keen sympathy is felt for his bereaved relatives.

The Partick Poisoning Case.—With reference to this case, reported in a former impression, we understand the explanation to be as follows:—Some eighteen months ago the Partick retail druggist ordered from a wholesale house *tinct. acteæ rasemosæ*, which was supplied as such, being in due course put into the special bottle for this preparation. It would seem that this preparation is not frequently prescribed. The medical practitioner prescribed acteæ rasemosæ tincture, which was accurately enough dispensed by the assistant, the contents of the bottle being assumed to be the drug in question. Subsequent inquiry, however, revealed the startling fact that the contents of the bottle were *tincture of aconite.* Should the retail druggist be able to prove this, it is clear that no blame whatever can attach either to him or his assistant. He will doubtless find it difficult, however, after so long an interval, to shift the responsibility.

Glasgow Death-Rate.—For the week ending with Saturday, the 7th inst., the death-rate of Glasgow was 28 per 1,000 of the population. This is the same as in the previous week, the figure for the corresponding weeks of 1882, 1881, and 1880 being 22, 23, and 27 respectively.

Health of Edinburgh.—The mortality in Edinburgh for the week ending with Saturday, the 7th inst., was 70, and the death-rate 16 per 1,000. Diseases of the chest accounted for 36 deaths, and zymotic causes for 4, of which 1 was due to fever, 1 to diphtheria, and 1 to measles, the intimations of these diseases for the week being 6, 1, and 76.

Proposed Cottage Hospital for Hawick.—For some time arrangements have been in progress for the establishment of an hospital and dispensary in Hawick, and there are now signs that the object of the promoters will be attained. A year ago a number of gentlemen formed themselves into a committee for the purpose of collecting money, and to carry on the work. That committee has been signally successful, and there is now in hand a substantial endowment fund. Ladies in town and district are at present organising a "Fancy Fayre," which is expected to eclipse all similar exhibitions hitherto held on the Borders, and which will be opened in August by the Countess of Dalkeith. By this it is hoped the fund will be largely increased, and building operations will be immediately commenced.

Correspondence.

"SHIP SURGEONS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Perhaps you will allow me to make a few observations on the above *questio vexata.*

I have had some experience ashore among that class from whom emigrants are drawn, and I have had also a little experience as to their treatment on board an Atlantic liner. From that experience I can say honestly that the emigrants on board ships belonging to the line I sailed on are treated infinitely better than they would be at home—that they are better fed and cared for in illness than they would be in either England or Ireland, in the station of life to which they generally belong. I fail to see the hardships of ship surgeons as compared with their brethren in Her Majesty's service, or in the Poor-law service. For my part I think a surgeon who is what he ought to be is treated with every consideration. I found no difficulty in obtaining anything I wanted for sick emigrants, beef tea, arrowroot, chicken, wine, &c.

I think what is really wanted to make the surgeoncies what they ought to be is to make it a *sine quâ non* that no person should be allowed to take charge of an ocean steamer who was not fully qualified, and who had not been in practice for at least five years; that surgeons should get an increase of say two shillings and sixpence a day for every five years' service; and a pension after twenty years' service.

I am, &c.,

WILLIAM DONOVAN, L.R.C.P., L.R.C.S. Ed.,
Medical Officer of Health, &c.; sometime Surgeon Cunard Service.

Whitwick, Leicester, June 30, 1883.

◆

FOREIGN DEGREES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I should be glad if Dr. Hardwicke would answer the following questions:—

1. Are the examinations at the different foreign universities conducted in English, or the language of the country?
2. Do these universities insist upon a year's, or more, residence and attendance upon certain courses of lectures?
3. Do the degrees conferred upon Englishmen, or other foreigners to the country in which the university is situated, give such graduates equal rights and privileges to practise in such countries as are enjoyed by the native graduates?
4. If the examinations are "thorough" and *bonâ fide*, why should Englishmen go abroad for a degree which they might just as easily obtain at home?

Home graduates have every right to be protected against the injustice of having men entitled to register degrees which are not really the equivalent of those they hold. It is essential that satisfactory guarantees should be given, in the case of foreign degrees, that to obtain them, the same difficulties should be encountered as in our home universities. Once allow them to be registered, and one may safely predict that the degree would be alone put forward, and no stress be laid on the place it was taken at. The British public are not very discriminating. To them all M.D.'s are alike. Some foreign degrees are, when taken on the same footing by Englishmen as by natives, quite up to the very highest standard, but to obtain them, an intimate knowledge of the language, attendance upon so many courses of lectures, and to pass the examination in the language of the country, are necessary. But this has not been the case with all the men who boast a foreign degree. Excuse my troubling, and allow me to thank you for your "carefulness, and I think very clear perception," in dealing with the merits of Dr. Hardwicke's claims. I hope no rash step may be taken by those in authority in this question. No one will call in question the merits of a degree from one of the old-established foreign universities, where *thorough* merit is insisted upon in the candidate, and the degree conferred carries with it all the privileges enjoyed by a native; but the assurance that such is the case is essential.

I am, &c.,

AN INQUIRER.

◆

ESPRIT DE CORPS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I request you will insert in the next publication of your paper the following statement:—

I resigned the appointment of surgeon and agent to the Admiralty 20 years since, as on being appointed thereto, after the demise of the late agent, I considered it derogatory to my profession to retain it at the small fee of 2s. 6d. per visit; and on representing my reason for so doing to the late Admiral, then Captain De Courcy, I was at once installed at a respectable remuneration, and continued to act unmolested as medical attendant on the Coastguard and naval patients, with the unqualified approval of all parties, until Dr. —— applied for the office at the rate on which I had previously declined to act, viz., 2s, 6d. ! ! Alas, for the honour of our noble profession! Well may we exclaim, "What a falling off!" and what a cheerless presage for the hard-worked, respectable doctor who tries to uphold his position as he considers it his *sworn duty to do.*

Yours, &c.,

Belmullet, July, 1883. JAMES MULLANY.

◆

SEA SICKNESS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In another medical journal I have read with amusement the experience of a brother practitioner, evidently in charge of emigrants—the various treatments he observed by sea-sick people from oranges, lemons, champagne, creasote, soda, Worcester sauce, hydrocyanic acid, bromides, up to curry, and, no doubt, a host of other infallible remedies so-called, and all evidently of no use. The sufferers, when they get, as a nautical phrase describes, their sea legs, all is well. As an old wide-world traveller in her Majesty's military medical service, I learnt experience on the point of sea-sickness, and observed "the simplicity of the laws of nature"—"the causes" in various illnesses; sea-sickness one. I have recommended many for years past the following:—When you feel the motion of the ship, and depressed nausea follows, take a tumblerful of tepid fresh water, gulp it down at the hands of the steward on board. Very shortly the stomach will retch and vomit the water; relief follows; and in half an-hour take a tumbler of cold fresh water; the stomach remains quiet. Without going into the medico-scientific reason of this treatment, which must be apparent to medical men, and without writing a pamphlet on it, results are true as I write. A few years ago, crossing from Jersey in a Channel steamer, I induced several passengers to adopt my wishes on leaving Jersey, and the thanks I received on entering the Southampton water were appreciated by me, as I acted most disinterestedly for sick passengers. I was asked by many gentlemen for my card, but I refused, not naming even my profession. One gentleman, with his wife and daughters, insisted on my card; I gave it. Shortly afterwards a diamond ring, worth at least fifty guineas, reached me as a slight token of gratitude. Let other sea-sick passengers follow my plan of treatment, and they will thank an unknown friend in their hearts.

I am, Sir, yours, &c.,

A MILITARY PHYSICIAN (retired),

London, July 16th, 1883. M.D., M.R.C.P. London.

Literature.

INSANITY: ITS CAUSES, PREVENTION, AND TREATMENT. (a)

THE apology offered by the author for the publication of this short study of a great subject is that it deals with matter of surpassing interest, inasmuch as mental maladies may, at any time, attack our nearest and dearest relations. But such an apology for a medical work can only be accepted when some new light is to be thrown on the absorbing topic, or when some practical assistance is to be afforded in the treatment or prevention of the maladies which threaten our domestic peace. And in neither of these respects does Mr. Harris's treatise on insanity justify its existence. It does not in any way advance the pathology of the brain and nervous system; it introduces no instructive novelties in the arrangement of ascertained facts, and it has no new word to say on the prophylaxis of mental disorders or the management of the insane. There is, indeed, some difficulty in understanding to what kind of audience this treatise is addressed. It is so sketchy and superficial that it cannot be seriously intended for medical men who have in their hands the standard textbooks on mental medicine, and have access to the copious literature of the subject, and it is impossible to believe that it is meant for the general public, as it contains disquisitions on the uses and modes of administration of chloral, Indian hemp, digitalis, nitrate of silver, liquor hydrargyri, bichloridi, and other dangerous drugs which ought only to be employed by a medical man, and directions for artificial alimentation by the mouth, nose, and other processes, which no one save a medical man ought ever to attempt. The little book fills up no gap, supplies no want, and opens up no new ground, and we can only suppose that Mr. Harris has arisen from a diligent study of that special branch of medical practice to which he is devoting himself so brimful of knowledge that an overflow was inevitable, an overflow the result of which is now before us. But overflows are generally wasteful; and we cannot say that this one is any exception to the rule. When Mr. Harris has studied his subject still more deeply, he will perhaps see reason to modify some of the opinions which he now so confidently expresses on questions on which some of the ablest and most experienced men in his department hesitate to pronounce judgment. He possesses zeal in his calling, and a vigorous style of expressing his ideas, and if he will shun speculation and platitudes, and devote himself to the patient and precise study of disease, he will produce work that will secure a more favourable reception than is likely to be accorded to his thin and pretentious booklet on insanity.

(a) "Insanity: its Causes, Prevention, and Treatment." By William Harris, M.R.C.P., M.R.C.S., and L.S.A. London: Wyman and Sons. 1882. Pp. 90.

THE SURGICAL KNIGHTHOOD FOR IRELAND.

We understand that an informal meeting of the profession was held on Monday afternoon in Dublin—time not permitting to summon the profession to a formal consideration of the matter—for the purpose of considering the proposition to grant knighthood as a recognition of the status of the surgical profession in Ireland. The chair was occupied by the President of the College of Physicians, and the meeting was attended by many of the leaders of the profession, including the President of the Irish Medical Association. A memorial to His Excellency Earl Spencer was adopted, setting forth that the grant of knighthood as a recognition of the status of Medicine and Surgery in Ireland was without precedent, and inconsistent with the dignity of the profession. It was resolved that a deputation consisting of the Presidents and Vice-Presidents of the Colleges, and of the Irish Medical Association, together with such signatories of the memorial as might be able to attend, should wait upon the Under-Secretary on Tuesday, for the purpose of presenting the memorial for the consideration of the Lord Lieutenant, and urging its prayer upon the attention of the Government.

◆

THE MEDICAL ACTS AMENDMENT BILL.

On Monday last Mr. Mundella received a deputation, introduced by Mr. Hopwood, M.P., in opposition to the Medical Acts Amendment Bill.—Dr. J. Rogers said the deputation asked for an amendment of the Bill, so that the general practitioners throughout the country might be directly represented on the various professional educational boards; and that unregistered persons should not be allowed to practise.—Mr. Nelson Hardy said that he had examined every Medical Bill since 1870, and this one was the worst of any.—Mr. Mundella: You are the first person who ever said so.—Dr. Alfred Carpenter said that the profession had no voice in the management of the bodies to which they belonged in the new Bill.—Mr. Mundella said that, in future, there would be a representation; from John O'Groat's to the Land's End, the most important members of the profession had expressed their favourable opinion of the Bill. As to unregistered persons practising, the same restrictions against them, as now, would be continued. There had been in the past too many examining bodies, and the Bill provided for a uniform test for the education of men for the medical profession.

Whilst congratulating Mr. Mundella on his reply to Mr. Nelson Hardy's dictatorial presumption, we trust that the rumours which reach us of compromises to stave off opposition in other quarters are unfounded. We have pointed out from time to time a few of the amendments which would render the Bill acceptable to the great bulk of the profession, and these being granted, we hope with Mr. Mundella that the Bill will pass, notwithstanding Mr. Nelson Hardy's opinion that it is "the worst of any."

◆

Medico-Parliamentary.

HOUSE OF COMMONS.—Friday, July 13th.

MEDICAL PRACTICE IN THE ST. PANCRAS WORKHOUSE.

Mr. Hopwood asked the President of the Local Government Board whether his attention had been called to the statements of Mr. Walter Dunlop, medical officer of St. Pancras Workhouse, that "the inmates numbered about 2,000. He had to see every person on admission, and visit about 1,000 of them daily;" whether this gentleman is the same who asserted that he had vaccinated about 1,500 mothers within a few hours after their delivery; whether such numerous and responsible duties could be performed with sufficient care by one man; and whether he had yet expressed, or intended to express, his sanction of the vaccination of women in workhouses within a few hours after their delivery.

Mr. G. Russell said the Local Government Board had communicated with Mr. Dunlop, who had informed them that at a recent inquest he stated that the inmates of the workhouse numbered nearly 2,000; that he was medically responsible for 1,000 inmates, which included those in the sick, infirm, insane, lying-in, and nursery wards, which, with the exception of the lying-in ward, were visited by him daily. He had vaccinated 1,500 mothers within an early period after their confinement, a period varying from the seventh to the fourteenth day after delivery. All severe cases were relieved, not at the workhouse, but at the infirmary at Highgate, where accommodation was provided for 500 patients. The Board possessed no evidence that the duties were not properly performed. With regard to the last part of the question, he could only say that a similar question was answered on the 11th of last month, the effect of which was that the Local Government Board would be glad to see the risk of vaccination dissociated as far as possible from the necessary risks of confinement.

THE CHOLERA EPIDEMIC.

Lord E. Fitzmaurice stated that, having obtained the valuable advice of Sir Joseph Fayrer, the post of special medical officer to Egypt has been offered and accepted by Surgeon-General William Hunter, F.R.C.P. Honorary Surgeon to her Majesty. He is a gentleman of the greatest Indian experience, and formerly served in the Bombay Presidency in the service of that Government, from which, however, he has now retired. I am quite sure that the House will feel that her Majesty's Government have been fortunate in being able to secure the advice and assistance of a gentleman of his knowledge and experience. Orders have been given by the Minister of the Interiorand General Baker to those under them to facilitate the passage of doctors, provisions, and medicines to all places attacked, and in infected places special service has been organised by the railway administration for Government use.

HOUSE OF COMMONS.—Monday, July 16th.

THE CONTAGIOUS DISEASES ACTS.

Captain Price asked the First Lord of the Treasury whether, after the statement made by the Secretary of State for War, as to the alarming increase in the number of cases of contagious disease in Her Majesty's forces since the abolition of compulsory examination, he still adhered to his intention of endeavouring to pass this Session a Bill for the repeal of the Contagious Diseases Acts.——The Prime Minister in reply said that in the present state of public business he was unable to give a definite answer.

Notices to Correspondents.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Professor Jonathan Hutchinson's College of Surgeons, "Lectures on Diseases of the Tongue" are unavoidably held over this week; we hope to re-commence the course in our next.

THE TREATMENT OF FRACTURES OF THE PATELLA.

To the Editor of the Medical Press and Circular.

Sir,—Mr. Henry Parson is much too angry to be fair in his brief and artless note which you published this week. Indeed, I feel guilty in having ventured an opinion, so imperiously am I brought to task. Mr. Parson should, however, remember that when he throws the gauntlet of a new appliance he must be prepared, like other men, to submit to criticism, and neither shed tears nor impute motives. Either equally betrays a weakness somewhere. I am ignorant of having "mis-stated facts," and innocent of comparing Mr. Parson to a "sea captain;" but if, on the ambiguity of my phraseology, I have conveyed to him the impression of a "violent attack," I beg to express my contrition.

In my ignorance I had supposed, and hypothesis acts as a red rag to Mr. Parson, that "movement of knee" involved the upper fragment of the broken patella. I shall never make so rash a statement again. For such blunders, Mr. Parson tells me to "master the subject," and to re-read his article. I have done so, and, I say it in faltering accents, the more I read it the less I understand it. Mr. Parson says he never heard of me before: I am sorry to have to confess my ignorance of him; but, thanks, Mr. Editor, to your courtesy, we have both emerged from obscurity, and I pray that under the shadow of your wing we shall never have occasion to return to it.

Yours, &c.,

Liverpool, July 13. Robert Jones.

[*** This correspondence must now close.—Ed.]

J. D.—There is no book on Irish Poor-law medical law. The laws themselves can be found in the Irish Medical Directory, and in the official Dispensary Regulations, which will also be found in its pages. We shall be glad to answer any special question you put to us.

Dr. Kelly (Rotherhithe).—Your *erratum* did not reach us until after the journal was printed; the correction, however, was immaterial, and in no way alters the sense of the paragraph.

Dr. Gaston (San Paulo, Brazil) is thanked for his communication. If he will kindly forward the *Medical Reporter* of November 4th for reference, we shall be in a position to carry out his suggestion if deemed desirable.

Mr. McGeorge (Liverpool) is thanked for his offer, but our arrangements are already completed for the annual meeting.

THE POLITICAL WEAKNESS OF DOCTORS.

To the Editor of the Medical Press and Circular.

Sir,—Your annotation under the above heading (*Medical Press*, July 11th) is so timely and truthful that, did time and means permit, I would have some twenty thousand copies printed and posted to the profession throughout the United Kingdom. Heaven helps those who help themselves is a threadbare saying; and the profession of medicine neither will nor can expect any help from Parliament or the public till it takes to heart the story of Hercules and the waggoner. Both within Parliament and without, the country is so thoroughly drugged with law and lawyers that doctors and physic are ignored, and if a stray doctor arrives at Westminster we never hear of him there as a medical reformer. Within the last fifteen years Ireland has returned a few medical men to Parliament, England has sent two, and Scotland two, "but what are they among so many" representatives of law? And even these few are found quietly to subside into inaction or to league themselves with this or that party and lose their own identity, and the chances of benefiting the profession to boot. The Northumberland miners are more alive as to their wants. They pay their representative; and occasionally, when the particular interests of labour are not concerned, the member for Morpeth, with a strange idea of the views he professes, indulges his constituents with an occasional onslaught on labourers of another class—I mean the medical profession; *vide* his attack about three years ago in the House, his aider and abettor being a barrister. However humiliating the confession, doctors are *de trop* in these countries as politicians. I have a personal acquaintanceship of more than twenty years with a retired practitioner, a gentleman of eminent and multiform talents and attainments, and almost a centenarian in years, who bears a name well known as that of an orator and patriot; and if questioned, this gentleman will confirm my statement that doctors as politicians are nowhere. In France they manage these things differently. Doctors there take their places as legislators along with lawyers and clerics. But whether their country's good or their personal good is the driving power which urges them deponent sayeth not. Sir, in conclusion, permit me to say that, until some *esprit de corps* is created and fostered in our ranks, the profession will remain, as at present, the football of every politician, lawyer, publican, and pitman in the land.

Yours, &c.,

July 13, 1883. Pauvre Docteur.

Dr. Allen (New Orleans).—We do not remember the circumstance to which you refer. Thanks for your promise.

Mr. Makuna (Melksham).—We will look through the paper and give an answer in our next.

DISPENSARY TICKETS.

Granulation asks: 1. Is it necessary to send the minutes of a Dispensary Committee meeting for cancelling red tickets before the Board of Guardians, and if the medical officer of a district can legally sue for fees until the ruling of the Dispensary Committee is ratified by the Board of Guardians? 2. What fees, if any, is a doctor entitled to who is called to certify to the condition of a lunatic, the lunatic being in said doctor's district, but being compelled, in order to meet two magistrates, to go into a neighbouring district? In case the magistrates refuse to sign the necessary certificate for payment from Guardians, what course is open to the aggrieved medical man?

[1. Certainly not; the Guardians have nothing to say to the matter, and the medical officer can sue on a cancelled ticket with or without their assent. 2. By Sec. 10 of Lunacy Regulation Act, the magistrates are obliged to call in "the medical officer, or, if there be more than one, the nearest available medical officer of the dispensary district *in which they shall be at the time*." The medical officer of the district in which the patient resides only comes before the magistrates in case the local doctor is not to be had. In such case only can he receive a fee, and if the magistrates refuse to certify, the medical officer cannot recover his fee under any circumstances.—Ed.]

A New Licentiate.—We are unable to express any view on the matter.

SECRET DRINKING.

To the Editor of the Medical Press and Circular.

Sir,—In your impression of the 11th inst. a correspondent asks if the grocer's wine and spirit licence has anything to do with it. Indirectly it has, as the grocer sells spirits, &c.; but the publican has his private door to sell "tea and coffee;" and I know, for a fact, that several women go into the tea and coffee department, in the private room, at taverns, to get what?—brandy and soda, and gin and bitters, which they drink there on the spot, as they only go in "of course" to buy tea or coffee, which the publican obligingly keeps for them. It looks respectable, that department outside; and there is this to be said in favour of the grocer, that his licence does not permit the consumption of intoxicants on the premises. Once let a woman crave drink, she is incorrigible after; there is no sliding scale. Either good or fearfully bad is woman.

Yours, &c.,

One who knows by Experience and Knowledge.

July 13, 1883.

Vacancies.

Birmingham Children's Hospital.—Assistant Resident Medical Officer Salary, £40, with board. Applications to the Secretary by the 30th inst.

Downpatrick Lunatic Asylum.—Assistant Resident Medical Officer. Salary, £100, with apartments, rations, &c. Election, August 4th. (See Advt.)

Enniscorthy District Lunatic Asylum.—Medical Superintendent. Particulars as to duties and emoluments obtainable at Dublin Castle. (See Advt.)

Middlesex County Asylum.—Assistant Medical Officer to the Male Department, Colney Hatch. Salary commencing at £150, with board. Printed forms of application will be supplied on request.

Royal Free Hospital, London.—Junior Resident Medical Officer. Board and residence provided, but no salary. Applications to the Secretary by the 25th inst. (See Advt.)

Appointments.

Brady, J. B. J., L.K.Q.C.P.I., L.R.C.S.I., Honorary Medical Officer to the North Dispensary, Liverpool.

Bryan, F. C., M.R.C.S., Medical Officer for the Third District and Workhouse of the East Preston Union.

Butcher, J. O., a House Surgeon to the Dental Hospital of London.

Campbell, A., M.B., Examiner in Medicine at the University of Aberdeen.

Collier, W., M.A., M.D. Cantab., M.R.C.S., House Physician to the Wolverhampton and Staffordshire General Hospital.

Cotterill, J. M., M.B., C.M., F.R.C.S.E., Assistant Surgeon to the Royal Infirmary, Edinburgh.

Cripps, C. C., M.B., M.S. Durh., M.R.C.S., House Surgeon to the London Lock Hospital, Male and Out-patient Department.

Davies, T., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Machynlleth District of the Machynlleth Union.

Fagge, C. H., M.D. Lond., M.R.C.S., Physician to the Deaf and Dumb Asylum.

Hawkins, F. H., M.B., Resident Clinical Assistant to the Brompton Hospital for Consumption and Diseases of the Chest.

Heygate, W. N., M.R.C.S., Honorary Medical Officer to the Eastern Dispensary, Bath.

Jones, O. C., B.M. Oxon., House Physician to the London Hospital.

Malet, H. M.D., Medical Officer of Health for the Borough of Wolverhampton.

Wood, W. H., M.R.C.S., Medical Officer for the Nunney District of the Frome Union.

Army Medical Department.—Surgeon-General J. A. Woolfryes, M.D., C.B., C.M.G., has been granted retired pay; Surgeon-General J. E. Clutterbuck. M.D., has been granted retired pay.

Births.

Jack.—July 13, at Powysten, Bournemouth, the wife of Surgeon D. Morton Jack, M.D., I.M.D., of a son.

Marriages.

Auchinleck—Johnston.—July 11, at All Saints' Church, Hugh A. Auchinleck, F.R.C.S.I., York Street, Dublin, to Rhoda Elizabeth, eldest daughter of R. J. Johnston, Esq., Northampton.

Clarke — Taylor. — July 5, at St. Stephen's, East Twickenham, Ernest Clarke, M.B., B.S., of Blackheath, to Kate Litton, second daughter of John Hirst Taylor, Esq., of Cambridge Park, Twickenham.

Deaths.

Cox.—July 9, at Netley, Surgeon Thomas Cox, A.M.D., son of the late Thomas Cox, C.E., of Ardfinan.

Mein.—July 12, at 12 Glencairn Crescent, Edinburgh, Archibald Mein, Esq., M.D.

Peele.—July 13, at Ludlow, Alice Jane, daughter of R. de Courcy Peele, Surgeon-Major (retired) Indian Medical Service, aged 17.

Shanley.—July 9, at Strokestown, co. Roscommon, Michael Shanley, M.D.

Taylor.—July 10, at Albert Place, Warrenpoint, William Taylor, L.R.C.S.I., of Downpatrick, aged 33.

NOTES ON THE HISTORY OF EPIDEMICS OF CHOLERA.

Compiled by Surgeon-General C. A. GORDON, M.C., C.B.,
Honorary Physician to Her Majesty.

(*Continued from page* 45.)

IN 1543 cholera is stated to have been "exported from India."

In 1817 cholera reached Jessore from without. In that year the disease is believed to have "broken out" in remote places at short intervals of time. It travelled down the coast of India, often in opposition to a strong current of wind, but along the track of human intercourse. On that occasion it appears to have been restricted within the limits of India. In 1818 several families were simultaneously attacked; the disease, moreover, spread eastward beyond the limits of India. On other occasions, in that country and elsewhere, th edisease has been restricted within certain limits. It was so in India in 1871; its limitation to certain areas on that occasion, uninfluenced —according to the views of some writers—by facilities of communication between the affected districts and those that remained unaffected. In 1873 the epidemic extended along the Mississippi from New Orleans; it was, however, confined to the valley of that great river, and did not become general.

On other occasions the scourge has extended far and wide. In Europe to latitude 64° north, but apparently not beyond that limit. In America, from Mexico to Canada, the West Indies, and to the interior of the Western Continent.

In 1848, between the months of May and December, the influence of cholera reached from Moscow in long. 37° East to the southern part of the United States of America, in long. 90° West.

In India, the epidemic of one period may not only affect the area of a preceding epidemic, but extend beyond its limits. This happened in respect to the outbreak of 1827 as compared with the outbreak of 1825-6.

It may continue to a certain point, and there cease, without the presence of any particular circumstance capable of explaining why it does so. In 1632 the natives of Goa had a belief—from reports received—that the disease, having extended from India, over Persia, Syria, and Egypt, it disappeared in the African desert. In 1823 the epidemic which reached Russia from Persia died out at Astracan; that of Syria of the same year, died out at Damascus, and neither of them extended to Turkey or to Europe, although intercourse with both countries was unrestricted. In 1829 the epidemic having extended from Bokhara across the steppes of Tartary reached Orenberg, and there "died out." In 1831 the disease ceased to spread in Germany, and France remained unaffected till the following spring.

In 1858 the eastern coast line of Africa was severely visited; the epidemic, however, stopped short at the Zanzibar district, nor did it extend inland.

It has been stated that nowhere has the diffusion of cholera taken place more rapidly than the rate at which communication occurs between different localities. The history of the epidemic of 1832 in Paris, that of Kurrachee in 1846, and others in India and elsewhere, indicate that there are instances in regard to which the theory of diffusion of the disease by means of human intercourse—as far as such intercourse can be traced—fails to explain the occurrence of the epidemic in a particular locality, and its spread beyond it.

Prior to the outbreak of cholera in Paris, as above, that city was in constant communication with Germany, Holland and England, in all of which countries the disease had prevailed for upwards of a year. In the meantime, Paris remained free from cholera until the spring of 1832, when the disease suddenly occurred in that capital, the subjects of its earliest attacks coming from such different parts of the city, and belonging to such different professions that the probability was very remote that personal communication between them had taken place.

Diffusion or spread of cholera does not take place uniformly. When the disease becomes epidemic it seems rather to extend from particular centres, often passing over villages and towns in its apparent line of progress and at times subsequently attacking them. Places affected in one epidemic are on occasions visited by subsequent attacks; at other times they are for longer or shorter periods left exempt.

Isolated outbreaks of cholera may occur in localities far apart, the intervening tracts or districts remaining free from the disease. In 1818, cholera prevailed in Delhi and Meerut, the intermediate towns and villages meantime remaining exempt. On the same occasion the disease was not met with between Nagpore and Baitool, a distance of seventy miles, although it prevailed at both these places. In 1837, isolated outbreaks of cholera occurred in Mexico, in Italy, at Marseilles, Berlin, Prague, Coventry, and on board the *Dreadnought*. In the latter instance, the *Iphigenia*, moored under the stern of the *Dreadnought* remained free from the disease, nor did the disease extend to Greenwich, notwithstanding that both those vessels were moored directly off that place. Shortly afterwards, the disease ceased in Europe, and from 1839 till 1846 that portion of the globe is considered to have continued absolutely free from the disease in epidemic form.

In 1855, the diffusion of cholera in France took place, in some instances along the great thoroughfares and rivers; in other instances in such a way that it was impossible to follow it. The disease sometimes appeared in a particular locality, confining itself to a small number of persons, and then disappearing. In other instances it increased in violence, and spread in different directions from particular points. In India, the epidemic was described as extending over the country, apparently so capriciously that it was declared impossible to say whether it was propagated along the main lines of communication, extended by means of the prevailing winds, or in what way it became diffused.

In 1856, cholera prevailed simultaneously in Northern India, Brazil, Cape de Verd, South of Europe, Russia, and Sweden. In the first named territory it appeared suddenly, and without any visible cause, at several isolated points.

With regard to the epidemic in India, 1861, at one place the disease appeared to proceed along the line of the main road, then it branched off, passed over several villages, and attacked others more distant. In some parts of a particular district the epidemic prevailed with great virulence, at another it was less severe; neither in respect to this occurrence, nor as to villages which escaped, were there any apparent conditions to account for the circumstance. The epidemic suddenly appeared in the Bhurtpore district; from that place it spread north-westward and south-eastward to a certain point in either direction, and there suddenly ceased. It did not attack the troops in the Fort of Lahore until three weeeks after it had became prevalent at Mean Meer, nor when it did attack the former could any communication be traced between them and those in the latter place. "In Northern India the disease seemed to be diffused independently of all discoverable conditions."

In 1865, cholera was diffused over Yemen and Hadramat in Southern Arabia, and the Somali country in East Africa. This outbreak was looked upon as a diffusion of the epidemic which began in the lower provinces of Bengal in 1863, and thence spread over India in 1864-5. On this occasion, the disease was believed by some writers to have been imported by pilgrims into Yemen. In that year, the progress of the disease in various directions from Egypt was as follows, namely: Alexandra, 2nd June; Marseilles, 18th; Malta, 21st; Smyrna, 24th; Constantinople, 28th; Beyrout and Jaffa, 1st July; Cyprus and Ancona, 7th; Valencia and Dardenelles, 8th; Gibraltar, 18th; Damascus and Trebizond, 1st August; Sulina and Kustendji, 2nd; Tultcha, 4th; Novorossiisk, Caucasia, 9th; Podolia and Odessa, 10th; Aleppo, 11th; Palma, 19th; Erzerum, 22nd; Altenburg, Saxony, 27th; Kertch, 29th; Algiers, 4th September; Bagdad and Southampton, 17th; Paris, 18th; near Naples, 28th; near Trieste, 29th; Naples, 6th October; Guadaloupe, 22nd; Taganrog, 28th; Ward's Island, New York, 22nd November.

In 1867, it was considered that cholera was conveyed to Mooltan at a more rapid pace than that of ordinary traffic by pedestrians and bullock carts. On that occasion the disease was considered to have been conveyed the last two hundred miles by means of the railway.

In 1867-8-9, cholera seemed to affect groups of localities in Russia, some conterminous with each other, some isolated.

In 1869, it appeared simultaneously in places at some distance from each other in India, as for example at Jounpore and Goruckpore.

In 1871 the extension of the epidemic to Europe was traced to importation from Asia, yet it was only when the disease began to spread in Russia, that it also extended as an epidemic through Persia and Arabia.

In 1875 the epidemic of that year in India was more diffused than that of 1874 had been. Both of these were very unequally diffused over the different places affected by them, but in the mass the severity of the disease in 1875 was greater than that of 1874. In 1875 the diffusion of the epidemic in Central India was gradual. The places first attacked were along the main lines of communication at considerable distances apart; subsequently villages were attacked in groups.

Cholera has never appeared in America except after Europe had suffered first by it. It has never occurred in the West of Europe unless the Eastern part of the Continent had been previously under its influence, and not in the East unless connected with an outbreak in Turkey, Asia, Arabia, or Persia.

Lastly comes the question—Can the progress of diffusion of epidemic cholera be checked by any means yet discovered? The reply to this query is that once cholera has become developed as such, no human means can stop its progress. There are authors who describe that disease as "preventible." Doubtless there is evidence to support the conclusion that in particular localities, and under particular circumstances, outbreaks of cholera have, to all appearance been so prevented; but, on the other hand, instances are enumerated in these notes of places being left thus exempt by the epidemic without the intervention of any preventive means whatever, and as regards the *general* diffusion of an epidemic, a reply in the affirmative has yet to be given to the question—Can it be checked? This is a melancholy state of things considering all the boasted "triumphs" of sanitation. Unhappily it is true. Such terms as "eradicating," and "stamping out" cholera are merely abstract expressions. We can do neither. But we can be prepared for it in the event of its occurrence. And to this end the best endeavours of the medical profession and of the public ought to be directed. It by no means follows that cholera will reach us; but let us be prepared for such an eventuality.

◆

ON SOME IMPLICATIONS OF DISSOLUTION OF THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P., F.R.S.,
Physician to the London Hospital, and to the National Hospital or the Epileptic and Paralysed.

(*Continued from page 434, November 22nd, 1882.*

I will here recapitulate what has been illustrated by the hypothetical centre of seven terms. Nervous centres —we consider them as motor only—do not represent muscles but, or except as, movements. Each term or unit of a centre represents a movement of the *whole* region which the centre altogether represents; every unit is the whole centre in miniature—representation of

---

[*] I wish to acknowledge a strange blunder. In the foot-note to the title of the last instalment of this paper a correction of part of a previous foot-note on page 413 was made. No correction was needed. The foot-note (page 413) is quite right. For what is called "most voluntary" is rigidly synonymous with "least automatic."

generality. But each unit represents a different movement of the whole region; every unit is the whole centre in different miniature — representation of speciality. Mode of Representation and process of Localisation are only two names for one thing; method of Co-ordination is a third equivalent name. Hence, repeating the foregoing from another standpoint, we say that there is no Localisation in the sense that each unit of the centre represents only a part of the muscular region; each unit represents, or co-ordinates, the whole region. And there is no Localisation in the sense that every unit of the centre represents the whole region similarly; each represents, or co-ordinates, the whole region differently.

From such constitution of the centre it follows that destruction of any part of it produces some paralysis *throughout* the muscular region represented, and yet, from destruction of different parts, there are different kinds of paralysis throughout it; paralysis preponderates in some district of the region according to the particular part of the centre destroyed. The degree of paralysis is proportional to the quantity of the centre—the number of its terms—destroyed; the particular kind of it is according to the particular part—the particular terms—destroyed; total paralysis is loss of all or of most of the terms of the centre. Similarly, *mutatis mutandis*, for convulsion from the opposite kind of lesion (positive, or "discharging," lesion): *for the present we are ignoring secondary discharges* of healthy terms, by those morbidly highly unstable. In saying that each term represents the whole region differently, a gradually increasing difference in representation was assumed, as was imperfectly illustrated in our hypothetical centre. In that centre X is most represented at one extreme, Z most at the other extreme, and Y most in the middle. Hence the progress of paralysis from increasing extent of a negative lesion is a Compound Order, and a compound order of a different kind according to the particular part of the centre in which that lesion begins. There appears more paralysis in the part of the region suffering first, and also greater range of paralysis the more the lesion extends. From increasing extent of a positive lesion there is compound order of spreading of convulsion, and a different order according to the particular part of the centre first affected. There is more spasm of the part first engaged, and greater range of spasm. Here again we neglect secondary discharges. (a)

From such constitution as is ascribed here to centres comes the explanation that a muscular region imperfectly, and yet permanently, paralysed throughout, may be occasionally convulsed throughout. For some term representing the whole region may be destroyed when another representing the whole region is highly unstable. From it, too, we see how compensation results in cases of negative lesions. For, since each term represents the whole region, on loss of, say, one, there is yet representation of the whole region by the six remaining. We see, too, that compensation, sometimes "practically" perfect, can never be absolute, since no two terms represent the whole region in quite the same way. It follows, too, that there are degrees of compensation—from very great to none—according to the extent of the lesion. And, further, we see that, just as paralysis increases in compound order the more extensive the negative lesion, so compensation diminishes in compound order the more extensive the negative lesion.

Next, taking count of secondary discharges, which, so far in this recapitulation, we have ignored, we see how in cases of high instability of parts of centres there are, on their discharge, degrees *of the opposite* of compensation. I mean that whilst, on the one hand, to illustrate, loss of one term of the centre produces comparatively little paralysis throughout the region—there being compensation by the six remaining—on the other hand, excessive discharge of one term may, by its leading to secondary discharges of more or fewer of the other terms, convulse the whole region severely. There is, in the latter case, so to speak, "inverted compensation." In other words, more or fewer of the six terms which will compensate the loss of one may be made, when that one term is highly unstable, to co-operate in an excess.

All these different statements are really, in effect, statements of different aspects of one thing—Dissolution, using that term as the reverse of Evolution. Leaving now for a time our hypothetical centre, we pass on to see how the principles deduced apply to actual cases of disease.

If the last-mentioned two of the dicta—Compensation and its opposite Co-operation in excess—be true in principle, we have in them the solution of the difficulty that (1) whilst destruction of part of the highest motor centres produces little *negative* effect, (2) excessive discharge of such part produces (directly and indirectly) great *positive* effect. For example, a part of the highest motor centres (*a*) may be destroyed without obvious permanent paralysis resulting—many would say without any. I submit that there is universal slight paralysis from such lesions. On the other hand, an excessive discharge (*b*) beginning in a part of these centres, as in cases of epilepsy proper, convulses the whole body severely. There are not the obvious simple opposites—(1) paralysis from negative lesion, and (2) convulsion from positive lesion; but the *double opposites*—(1) *slight* paralysis, some say none, and (2) *severe* convulsion. If there be no paralysis in the former case, the contrast is all the greater. Now, we repeat the foregoing on what we call the double opposites in more detail and with some amendments.

As we said, each term of a centre represents in a different way from every other term of it the muscular region which the centre as a whole represents; each term *is* the whole centre in miniature, but in different miniature. The "region" represented by the highest centres (the climax of nervous Evolution) is the whole body; each of the innumerable terms of these centres, it is supposed, represents the whole organism in a different way from every other of the terms. Epilepsy proper is owing to "discharging lesions" in parts of these centres: we speak at present of severe paroxysms—of *le grand mal*. It is inferred that there are numerous epilepsies ("varieties" of epilepsy proper), as many, at any rate, as there are different "warnings" of what we call *the* paroxysms; for different "warnings" of necessity point to "discharging lesions" differently seated. No one denies that there are varieties of epileptiform seizures; these occur from differently seated "discharging lesions" in the middle motor centres. It would be very remarkable were there not differently seated "discharging lesions" in the highest centres, and hence many different epilepsies. If one patient's epileptic seizures always begin by an epigastric sensation, and another's always by a particular kind of vertigo, the "discharging lesions" must be differently seated in the highest centres in the two cases. We may be as certain of this as that the "discharging lesion" is in different parts of the middle centres in two patients, one of whom epileptiform seizures begin in his foot, and in the other's in his hand. Different epileptiform seizures have their particular places of onset, degrees of involvement of particular parts, and orders of spreading. It is supposed similarly that, in each epilepsy, the severe convulsion, although universal, differs somewhat in its exact onset, degree of involvement of particular parts, and order of spreading from the severe convulsion in any other epilepsy. *Mutatis mutandis*, for the effects of "destructive lesions," it is supposed that there will be different *slight* universal paralyses, according to the particular part of the highest centres destroyed.

(a) With strict accuracy we should say that the paralysis and spasm become gradually more decided over a greater range; the seeming discrepancy comes of the artificiality of the illustration, and allowance made for that, the principle stated holds good. We shall refer to this matter again.

(*a*) It has long been admitted that large parts of the brain may be destroyed without there resulting any striking symptoms. It has been said that there may be no symptoms in such cases. This is untenable unless on the supposition that some parts of the brain are without function, a supposition no one is likely to entertain.

(*b*) I find that the term "discharging lesion" has led to misunderstandings. It has been taken to imply that a pathological product discharges. Possibly such expressions as "discharging lesions *seated*" may lead to this notion; but surely that one is a very innocently transparent figure. I have been supposed to put forward "the theory of discharges" as the pathology of epilepsies, whereas I have expressly repudiated any such application of the theory. The correct statement of my opinions would be that the "theory of discharges" is *not* the pathology of epilepsies. The "discharging lesion" is an hyper-physiological condition of cells. Now, so far from confounding this with any pathological process, I have urged that the two should be most carefully distinguished; only by doing so can we, with clearness, seek the nature of the pathological process leading to the hyper-physiological condition of high instability; the morbidly high instability is one thing; the pathological processes (morbid alterations of nutrition) leading to it are doubtless many. We must have a term which is the opposite of destruction, or destruction of function, of nervous elements. I sometimes use the terms "negative lesion" and "positive lesion;" in one no or little energy is liberable; in the other an abnormally high quantity is occasionally liberated.

As will be seen, we have artificially simplified the subject in several ways, and especially by speaking of but a single centre. The explanations by aid of our hypothetical centre of seven terms are necessarily imperfect. In the just preceding remarks, referring to actual cases of disease, lower centres (middle and lowest) were implied by the term "highest centres." We now take count explicitly of three orders of centres—highest, middle, and lowest.

I have previously stated in this journal what I suppose to be the hierarchy of nervous centres according to the doctrine of Evolution. (*a*) I here re-state it in a better way. This scheme is, not, as I have in some former papers erroneously said, after the morphological divisions, into spinal cord, medulla oblongata, pons varolii, cerebral hemispheres, and cerebellum. It is an anatomical division. By anatomical I mean that it is after the different degree of complexity, &c., of representation *of parts of the body* by different centres. The nervous system is a representing system, and even the centres "for mind" represent parts of the body. The doctrine of Evolution repudiates all schemes which make piebald divisions into Ideational, &c., centres, and sensory and motor centres—all centres are sensory or motor, or both. Nor does it divide motor centres into centres for representation of movements, and centres for co-ordination of movements; the two things—representation and co-ordination—are really one. The whole nervous system is a sensori-motor mechanism, a co-ordinating system from top to bottom. The Evolutionist can take a brutally materialistic view of disease of any part of the nervous system, for the reason that he does *not* take a materialistic view of mind—does not confound nervous states with psychical states. The highest centres are only exceedingly complex, and special sensori-motor nervous arrangements representing, or co-ordinating, in the ways we shortly go on to show, the whole organism. The doctrine of Evolution has nothing whatever to do with the nature of the relation of psychical to the physical states of these centres; it simply affirms concomitance of psychical states with states of these centres. There is not the slightest incongruity in saying that the highest centres are centres co-ordinating impressions and movements, and in saying also that they are the anatomical substrata of psychical states; there would be in saying that activities of the highest centres *are* psychical states.

(*To be continued.*)

◆

THE TREATMENT OF INEBRIATES.

By JOHN W. MARTIN, M.D., M.Ch.

Sheffield.

The recent establishment of the Dalrymple Home for the cure of inebriates, under the auspices of the Lord Mayor of London, and the forcible article on the same subject, in the Philadelphia *Medical Reporter*, by Dr. Crothers, of Hartford, Connecticut, a well known authority, brings the question again prominently to the notice of the profession.

Dr. Crothers strongly advocates the establishment of places for the restraint, and proper treatment of habitual drunkards; and forcibly points out the inutility of fine, or imprisonment, as a means of restraint, in the case of these unfortunates. Indeed, he gives well marked examples of the pernicious effect of such punishment, in confirming, the hitherto comparatively speaking innocent drunkard, in vicious, and criminal habits. Dr. Crothers rightly views habitual inebriation, as a form of moral insanity, requiring proper scientific medical, and hygienic treatment. The object in view would be to restore both mind and body to a healthy condition. He would place them under a semi-military discipline; have them engaged during the day upon suitable aud remunerative labour, by means of which, the institution might be made self supporting; occupy their leisure hours with lectures, concerts, pleasant or instructive reading according to taste; and finally bring to his aid electricity, Turkish, and other baths, gymnastics, and every means by which new vigour could be imparted to enfeebled bodies, and enfeebled wills. The subject is one, about which the public mind is not as yet sufficiently instructed. It is one, however, that is certain to become in time, one of the leading questions of the day.

To propose a return to the old system of treating those who are mentally afflicted, by chains, handcuffs, and all the other horrors of bye-gone days, would raise a storm of indignant protest, from one end of the land to the other; and yet, the present treatment of inebriates, is, as far as the wisdom of the method concerned, quite on a par with the folly of our forefathers, in their treatment of the insane. The solemn, and indeed, one may also safely term it, wicked farce, of fine or imprisonment, goes on from day to day in our police courts. Men, and women, who, at the outset of their downward course, are covered with shame, when placed in the dock, or, when they find themselves compelled to associate with criminals, become used to the position, lose their remaining sense of self-respect, and rapidly descend, deeper and deeper into the mire of criminal acts, and criminal surroundings, until they become a permanent burthen to the state, as jail birds, or as dependents on workhouses; or they become canker spots for the spread of further evil, either through evil example, or through the still more dangerous influences of heredity, the morbid propensities of the fathers, or mothers, descending to the weak fibred or imperfectly developed child. The statistics given by Dr. Crothers, are most interesting. In 1879 in the State of Massachusetts, seventeen thousand five hundred and seventy inebriates were punished by fine or imprisonment. In New York State, in one year, over fifty thousand convictions for drunkenness were recorded, and so on, in all the cities and states in the Union, in like proportion.

Dr. Crothers says: "Inebriety, pauperism, insanity, and the criminal classes are steadily increasing. The number of commitments for inebriety is also increasing. The demand for jails, almshouses, and insane hospitals is greater now than ever before. Such institutions are crowded. This fact is startling, coming from the statistics of every jail and prison, *that from ninety-eight to one hundred per cent. of all commitments for inebriety the first time, return under similar commitments*, and become repeated until sent either to insane hospitals, or to die in almshouses." The dark colours of this picture require no comment. He goes on to point out the evil effect of imprisonment upon the already enfeebled constitution and will of the drunkard. "Confinement in jails or prisons removes the inebriate from alcohol, *but* places him in surroundings of physical and mental degeneration, from which recovery rarely follows. This is on the same principle, as the removal of typhoid cases to small-pox hospitals, or treating insanity by sending patients to the hall of the Stock Board in Wall Street, New York. Every case of inebriety is suffering from a low form of nerve debility, and general impairment of all the organic

---

(*a*) I should say that a very great part of this paper is nothing more than an application of certain of Herbert Spencer's principles, stated in his Psychology, were it not that I dare not risk misleading readers by imputing crudities of my own to this distinguished man.

functions. The brain is starved from defective nutrition, alcohol has broken up the healthy action of the nerve centres, and conditions of profound degeneration of mind and body are present." "Prison diet always leaves a low state of nutrition, and opens the door for many diseases." "Absence of open air, proper exercise, sunlight, &c., all lower the tone and vigour of the organism. The physical influence from the wounded pride merging into despair, and the enforced association with the lowest grades of humanity, leaves an impression more or less permanent." "In jails where inebriates are confined for short terms, the inmates are allowed free intercourse. The results from this contact, are familiarity with the most degrading influences, and the sympathy of a class that are outlaws to all that is good and true." "All medical means, all physical influences, and all help from surroundings and conditions, being wanting, they are replaced by the worst possible combinations of exciting and predisposing causes, forming a low chronic state that is incurable." "From the economic stand-point the penal treatment of inebriates is a most extravagant and vicious system of legislation."

The thoughtful mind finds no difficulty in acknowledging the truth and force of these remarks; the only wonder is that they are not more generally and widely accepted and acted upon. We no longer allow children to sink unaided into the hideous depths of a criminal life; they are committed to reformatories for a certain term of years, removed from those influences by which their characters were becoming warped, and in the end, in the case of a large majority, are turned into honest and law-abiding citizens of the State, a source of strength and revenue, instead of weakness and expense. Surely this question is one far worthier of consideration at the hands of our statesmen and legislators than many of those measures and questions by which their time and attention is at present occupied. It is at least worth careful inquiry at the hands of a Royal Commission, before which evidence could be adduced from—1. The judges, recorders, and magistrates of the land. 2. From chief constables and constabulary authorities, and governors of prisons. 3. From superintendents of the great lunatic asylums. 4. From medical men, clergymen, and others, who from their position might be able to throw light on the subject, as to the effects of habitual drunkenness upon the crime statistics in all its ramifications, and upon the health and well-being of the population at large. Enough, we are satisfied, would be shown to justify the first outlay upon reformatories for the unfortunates who have become the victims to habitual inebriation. Such outlay would be well repaid by the general diminution of crime, and the institutions themselves might be made self-supporting. The order of events might be—1st, a warning; 2nd, a *heavy* fine; 3rd, commitment to a reformatory. In no case should the drunkard be debased by intercourse with the ordinary criminal classes. Their cases should be dealt with separately, and altogether with the object in view of encouragement to reform.

We believe something must be done in another direction as well. Whilst punishing, or, rather, trying to reclaim, the drunkard, we ought to take every means to increase the sense of responsibility on the part of those who supply intoxicating liquors. We know this part of the subject is one surrounded by many and great difficulties. It is repugnant to our feelings to interfere to too great an extent with the liberty of the subject, or to hamper any trade by vexatious restrictions. At the same time, drunkenness is a national evil and a national disgrace when it prevails, and one which ought to be met firmly, both in the case of the individual who has been unfortunate enough to contract the habit, and of the publican, whose interest it is that as much should be sold as possible. It would be an extreme measure, perhaps, and one that at present, at all events, there is no chance of imposing, but one which, were it imposed, would, we are satisfied, prove a very efficient check upon the evil—*i.e., the imposition of a sharp fine for every clear case of drunkenness discovered upon the premises of a publican.* The mere presence of the drunken person should be the offence, not the fact that drink has been served to him.

What the members of the temperance party should aim at is not the suppression of the liquor traffic altogether, since that idea is clearly Utopian, but, on the one hand, so to reform the legal method of dealing with inebriates as to teach them self-restraint and avoidance of their enemy; on the other, to compel the vendors of intoxicating liquors to see that no drunkenness occurs or exists on their premises.

When one reflects that to drunkenness can be clearly traced murder, manslaughter, suicide, savage assaults, accompanied often by the infliction of irreparable injuries, wife desertion and neglect of families, pauperisation, disease both in the individual and in the offspring, and a long train of other attendant evils, the most ardent lover of liberty will hardly quarrel with the most stringent measures that could be adopted to enforce *moderation*. Total abstinence we do not believe can ever be attained, nor do we think it needful. It is more laudable to control the appetite than to deny it altogether.

Clinical Records.

NEWCASTLE-ON-TYNE INFIRMARY.

Case of Double Optic Atrophy with Cerebral Symptoms, the result of gazing at the Sun.

Under the care of DR. DRUMMOND.

K. S., æt. 11, a bright, well-nourished girl, was admitted into the Newcastle Infirmary on April 19, 1883, complaining of dimness of vision and weakness in the legs. Her mother stated that in July, 1881, she first observed a change in the child, who previously had enjoyed good health. It was noticed at school that she no longer learned her lessons in a satisfactory way, for which neglect she was chastised on several occasions. At length it was discovered that her sight was impaired, when it transpired that, two or three weeks previously, on a bright, hot day, she had engaged in a sun-gazing competition with some other children, she being victorious, having looked at the sun for "nearly twenty minutes." The effect of this prolonged exposure of the retinæ to the rays of a mid-summer sun was, as was gathered from the patient's own statement, that she became "stone" blind, and was obliged to grope her way home along the wall. By the end of two days she had partially regained her sight, and by degrees she could distinguish objects, though imperfectly. A month after the sun incident, headache and vomiting were complained of, and then for some weeks "she completely lost her memory." (a) The subsequent history is uneventful. The headache and vomiting continued for some months. A year and a half after the commencement of the illness paresis of the lower extremities made its appearance, which subsequently developed into incomplete paraplegia with a tendency to rigidity. The amaurosis, which had somewhat improved, though the child was all along purblind, became gradually worse up to the date of admission into hospital.

Present condition.—Patient walks with difficulty, the gait being more or less *spastic*. She complains of nothing, as she lies in bed, but dimness of vision; she has not felt the headache for about six months. The left eye is almost completely blind, she can only distinguish light from darkness with it. With the right objects are seen very indistinctly, but fingers held before her face can be counted. Pupils respond to light and efforts of accommodation. The ophthalmoscope shows atrophy of both discs, most advanced in left eye. The reflexes of the lower extremities are those usually found in descending degeneration of the lateral columns, viz., slightly increased plantar reflex, ankle clonus, and increased patellar-tendon jerk.

(a) It is impossible to say distinctly what occurred during these few weeks; though the child's statement suggests an attack of acute meningitis with loss of consciousness, the mother's account fails to support such a view.

Remarks by Dr. Drummond.—In this case the amaurosis seems to be directly the result of over-stimulation of the optic nerves and retinæ. Several examples are on record of cases of optic atrophy following sun-stroke, the atrophy and consequent blindness occurring as the result of meningitis, or cerebral congestion, due to heat. But in the present case it will be noted that the cerebral symptoms only developed about four weeks after the exposure to the sun's rays; and further, on careful inquiry no history of heat-stroke, in the usual acceptation of the term, could be elicited. It is, therefore, probable that swelling of the optic nerves and papillæ was the first feature of the morbid process.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

Malignant Pustule—At the Société de Chirurgie, M. Reclus communicated a case of malignant pustule which healed spontaneously. A young man, whose employment was carrying meat to the hospital, observed a small tumour on the side of his neck. On the third day he had a rigor and felt ill; on the fifth day, when M. Reclus saw him for the first time, an eschar was visible, surrounded with an areola of inflammation and the characteristic ring of vesicles. The ganglions of the neck were also engaged, and the treatment up to that time consisted in simple poultices. The nature of the affection was put beyond all doubt by inoculation. M. Reclus inoculated a serpent with the virus with a positive result. The poultices were continued and the patient got well very rapidly. In conclusion the author said that he was at a loss to explain this cure unless it were that the individual was refractory to the infection of charbon. M. Despres said that he knew of two similar cases, and would not contest the possibility of a spontaneous cure, but, at the same time, there was a doubt in his mind as to the genuineness of the case under consideration. It was remarked that the ganglions at the root of the neck were inflamed, a fact which he never witnessed, although he had seen many cases of charbon. M. Championnière did not consider that the cure was exactly spontaneous, inasmuch as extract of walnut leaves were used. In his mind walnut leaves were a powerful antiseptic, and consequently might have had a good effect on the disease. In any case spontaneous cure was not rare, on the contrary, in Russia it is frequently observed, especially when the pustule is situated elsewhere than on the face. M. Pozzi said he observed two cases himself of spontaneous cure, in one of which he could not find any bacterides. He was inclined to think that they were what he would call benign malign pustules in which these bacterides were absent. Consequently, he thought, that the presence of the micrabe should be considered as a pathological sign of the gravest form.

Treatment of Croup.—M. Jules Simon, of the Hopital des Enfants Malades, treats croup as follows:—As soon as the malady is diagnosed he touches the throat with lemon-juice, or a solution of muriate of iron every two hours. Every three hours he washes the part affected with a solution of borax (two drachms to the ten ounces). At the same time the atmosphere of the room is charged with atomised phenic solution, a stimulant nourishment is given, and three to five drops of tincture of iron administered every three hours. When dyspnœa becomes apparent an emetic is to be given, but if the symptoms are not relieved tracheotomy must be performed without delay. The results of the operation are not, however, very satisfactory, as when the child is under two years a fatal termination is the rule, whereas above that age one out of five recovers. The after treatment consists in placing a piece of tarlatan over the canula, warming the room, and administering beef tea and tincture of iron. The removing and cleaning of the canula should be done by an experienced person, it might be definitely removed after the eighth or tenth day. M. Simon considers that chlorate of potash is of little use in croup.

Department of Lunacy.

THE NEW COMMISSIONER IN LUNACY.

The announcement that Dr. Reginald Southey has been appointed a Commissioner in Lunacy, in succession to Dr. Nairne, resigned, cannot be received with unmixed satisfaction by those who have at heart the interests of the insane and of that special branch of the medical profession engaged in lunacy practice. Dr. Southey is an able and sound physician, who has had large experience while on the staff of one of our great metropolitan hospitals, and who has given evidence by his writings and lectures of an intimate and practical acquaintance with pathology and medicine. He will unquestionably bring to the high office for which the Lord Chancellor has selected him, an intellect trained in scientific pursuits, a mature knowledge of men and affairs, and a distinguished professional reputation. And yet, in spite of these excellent qualifications, it may be doubted whether he is well-fitted for that office, for he lacks that special knowledge of mental disease which is, in our judgment, an indispensable requisite in a medical commissioner in lunacy. It was hoped that the storm of disapprobation which was raised some twenty years ago by the appointment of Dr. Nairne, whom Dr. Southey has succeeded, and who was like him a London hospital physician without lunacy experience, would have prevented the repetition of such a mistake, and general regret must be felt that the plain principle which should regulate such public appointments should have been again disregarded. That principle we take to be, that the person appointed should have a special aptitude for the work which he is to undertake, and such an acquaintance with it that he shall not have, while in office, laboriously to acquire its rudimentary conditions. Insanity is a generally-recognised and well-defined branch of medical practice. By the unique symptoms which characterise it, the legal disabilities which it involves, and the peculiar methods of treatment which it requires, it is separated from general medicine; and so varied and complex are its phenomena, that it demands the undivided study and attention of any professional man who pretends to deal with it. This is all but universally recognised. General practitioners invariably and gladly avail themselves of special aid when a case of insanity occurs in their practice, and general physicians do the same thing, pointing out, in any case of mental disease that may be brought to them, that it lies beyond their proper province and that the skill and insight of a trained specialist are necessary for its successful conduct. We fancy that Dr. Southey himself would have declined a month ago to undertake the responsibility of a case of acute suicidal mania taken to his consulting-room as unhesitatingly as he would have refused to operate in a case of cataract, or to give a diagnosis in a case of uterine tumour. And yet the physician who would have shrunk from the care of one case is now called on to deal with thousands, and to supervise a body of professional men whose knowledge of insanity must far transcend his own. It is impossible for anyone under such circumstances to act with perfect calmness, confidence, and judgment; and it might well be argued that public security is put in some jeopardy while the new Commissioner is learning his duty. It seems to us of paramount importance that a Commissioner in Lunacy should have a thoroughly practical acquaintance with mental disease and lunatic hospital administration, so that he may be prepared to decide difficult questions of sanity or insanity, and command the respect of lunatic asylum officers of every grade. The Board of Commissioners in Lunacy is not too strong as at present constistuted. Care should have been taken, on the occasion of Dr. Nairne's retirement, to fortify it by the appointment of some one whose competency would have been at once acknowledged in every asylum in the country. The names of several gentlemen engaged in lunacy practice might at once be mentioned who possess all the qualifications necessary for a Commissioner in Lunacy, and who would have obtained at once in office that deference and obedience which never fail to wait on knowledge and ability when placed in power, but which are slowly and grudgingly accorded even to the highest ability when not combined with experience. Not the least cogent objection to Dr. Southey's appointment is that he has been introduced at a high point into a special service, and has been promoted to a position of dignity and emolument, over the heads of those who have been toiling for years in this department, and have looked perhaps to the position which he now occupies as a possible reward of their labours. The prizes of lunacy practice are few and meagre, but such as they are they should be reserved for those who have fairly earned them by conspicuous ability and long devotion to duty. If this be not done, but if the highest appointments be given to outsiders who have not borne the heat and burden of the day, then lunatic asylum service will fall in professional estimation and cease to be attractive to young men of the highest talent and promise, much to the detriment of the insane, who must always be in a large measure dependent for their comfort and welfare on the character and standing of the medical officers of the asylums in which they are confined.

The staple argument in favour of the appointment of a general physician as a Commissioner in Lunacy is that he brings to his work a free and open mind, without any of that bias which special study is supposed to produce. But it is forgotten when this argument is urged that the ingenuousness and absence of prepossession which are desired are already secured to the Board of Lunacy in a bounteous degree in the persons of the barrister Commissioners, who are free not only from special but from medical bias. The visitations of the Commissioners are carried out by a barrister and doctor together, and it seems only reasonable to ask that, as ignorance of insanity and common sense are represented by the one, technical knowledge and skilled insight should be represented by the other. There are only three medical Commissioners, and each of them ought to be familiar with that group of diseases which supplies them with all their official work. Lord Shaftesbury has conferred great benefits on his countrymen, but he is the author of one dictum which has already done some mischief, and which is perhaps destined still to work evil. He it was who said that insanity is a fact about which any ordinary man is quite as well able to judge as any medical man. Insanity is certainly a fact, but it is a fact just in the same sense that cancer of the stomach or pernicious anæmia is a fact; and the opinion of an ordinary man in a case of insanity is just as valuable as it is in cases of these occult diseases. Carried out to its legitimate conclusion, Lord Shaftesbury's view would lead us to dispense with medical certificates in cases of insanity, and to substitute lay-men for medical men as the governors of lunatic hospitals. But his Lordship is not prepared for all this, and the Board over which he so ably and disinterestedly presides not only systematically recognises insanity as essentially a medical question, but as essentially a specialistic medical question. It would not sanction nor approve of the appointment of any one as medical superintendent of the smallest lunatic asylum in the country who had not had special training in the treatment of insanity and asylum management. Why, then, it may be asked, should it be less rigourous and exacting as regards the qualifications of its own members? Why should it, without protest, receive as a Commissioner one who, however able and accomplished he may be, has had no special training of any kind? That Dr. Southey will prove an useful, dignified and urbane Commissioner we have no manner of doubt; but his appointment is one which calls for criticism, and that will not we trust be converted into a precedent. When an alteration in the law takes place, it is to be hoped that the number of barrister Commissioners will be reduced, and a substantial addition made to the number of medical Commissioners, upon whom the heaviest part of the work of the Board must always fall.

◆

HONOURS TO DISTINGUISHED OFFICERS OF THE ARMY MEDICAL DEPARTMENT.

ON Thursday last the President (Mr. J. W. Wheeler) and Council of the Royal College of Surgeons of Ireland assembled in the Boardroom of the College for the purpose of conferring on Surgeon-General Crawford, Director-General of the Army Medical Department, and on Surgeon-General Sir James Hanbury, K.C.B., Honorary Fellowships of the College, in recognition of their distinguished careers, especially in connection with their services in the Egyptian and other wars. There was a large and enthusiastic gathering, the President, the Members of the Council, and the Examiners of the College wearing their robes; and the members of the Army Medical Department appeared in the uniform of their respective grades in the service.

Dr. Mapother, having introduced Surgeon-General Crawford to the President,

The President said: Surgeon-General Crawford, Director-General of the Army Medical Department, the pleasing duty devolves upon me, as President of this College, of conferring on you its highest degree, the Hon. Fellowship. This pleasure, Sir, is greatly increased by the fact that I am about to confer this distinction on the head of a department I once had the honour to belong to. (Applause.) There are two classes of persons upon whom the Royal College of Surgeons in Ireland confers its Hon. Fellowship—one, medical scientists, men who have devoted their talents to science alone, without, perchance, themselves obtaining any practical results. The other class, under which you, Sir, come, are those who from scientific knowledge and research produce practical results in surgery. Sir, this College is peculiarly jealous of its highest degree, the Honorary Fellowship, and on no one is this distinction conferred until his claims for such distinction have been deliberately, carefully, and well considered. We have, Sir, followed your brilliant career from the time you entered her Majesty's service. (Applause.) We are aware of your services in the Burmese War. We know how you performed your arduous duties at the storming and capture of Rangoon and Whitehouse redoubt; we know that not only in Burmah, but in the Crimean campaign, you were instrumental in saving many valuable lives through your scientific knowledge of surgery and its auxiliary branches. (Applause.) We are cognisant how prominently you were mentioned in despatches in the Afghan campaign, and not alone for your valuable administrative powers. I have read your elaborate reports when principal medical officer to the Southern Indian Field Force in Northern Mahratta. I have read, Sir, in the medical history of the troops who served in Turkey and the Crimea, written by the talented brother of your illustrious representative in Egypt, Sir James Hanbury, your reports on the health of your regiment, the 18th Royal Irish. (Applause.) I have read your successful operations, and seen your statistics. I have read with great interest your estimate of how far sudden change of climate was prejudicial to the various elements of which your regiment was composed. Nor can I omit your contributions on scurvy, diarrhœa, and dysentery; your sanitary and topographical report on Secunderabad, your exhaustive contribution on the examination and physical disabilities of recruits, and your special report on the hospital organisation, sanitation, and medical history of the wars in Afghanistan of 1870-79, '80. And lastly, Sir, we are all aware of the admirable arrangements you made for the sick and wounded in the Egyptian campaign. (Applause.) Sir, I cannot allude to that without expressing great admiration for the perfection of those arrangements, and for the astuteness and sagacity in your selection of those who were to carry out such arrangements and organisation as you conceived to be necessary; and, although it may be expedient to modify in minor details the departmental system which the Director-General has advocated, yet this system could not have worked better than it did in Egypt. Never were the wounded so quickly carried off the field—(applause)—never so promptly attended to, never a war in which men were better medically attended to, never was the mortality so small in any campaign of comparative magnitude. (Applause.) Gentlemen, I could recount example after example where the administrative powers of the Director-General and his scientific knowledge of surgery and its auxiliary branches has prevented the spread of disease, has saved life, has lessened suffering, has mitigated misery; but I feel this is better known than I can express it, and will conclude by saying that the Royal College of Surgeons in Ireland, anxious to confer honour where honour is due, has awarded to the Director-General of the Army Medical Department its highest degree, its Honorary Fellowship. (Applause.)

The President then handed to Surgeon-General Crawford a morocco case, in which the certificate of Honorary Fellowship was enclosed.

The President, addressing Surgeon-General Sir James Hanbury, K.C.B., said: Sir, a similar pleasure is afforded to me, as in the case of the head of your department, of informing you that the Hon. Fellowship is now about to be conferred on you. I need not again refer to those on whom the honour is conferred, but when you see the list, the very limited list, of distinguished names to which list your name will now be appended, you will more fully understand how few obtain this distinction. As in the case of the Director-General, we have followed your career, and appreciate your services. We have evidence of your efficiency when principal medical officer in the Afghan war of 1878, 1879, and 1880. We know of the Bozar Valley expedition, and your march from Cabul to the relief of Candahar, and of the battle on the 1st of September—how excellently you performed your arduous duties, and how deservedly you were mentioned in despatches, and decorated with the Order of Companion of the Bath. (Applause.) As principal medical officer of the Egyptian campaign, we congratulate you warmly for the manner in which you carried out the hospital organisation. We are fully alive to the difficulties that beset you. The way in which you conducted your comprehensive medical work cannot be spoken of too highly. Knowing something of Egypt as I do, where sanitary arrangements are not considered necessary, it cannot but be a matter for universal admiration the rapidity with which you established hospitals in empty buildings, almost pest-houses, where works of drainage and water supply had to be done, and ventilation had to be provided—the Palace Hospital at Ismailia—for although the Khedive's Palace was only handed over on the 22nd of August, and engagements took place on the 24th, 25th, and 28th, yet, on the 25th, the wounded were all in bed, and surgical operations being performed. You established hospitals at Alexandria, Ramleh, Ismailia, the Citadel Hospital at Cairo, and a camp hospital at Ghezireh, also an hospital at Abasseyah Barracks, and another at Kassassin Lock, which received the wounded after the battle of Tel-el-Kebir. The preparations you made for the sick in the various actions fought or anticipated is an additional proof, if such were required, of the wisdom of the Director-General in selecting you for such a duty. (Applause.) Sir, every practical person must look with great satisfaction at the statistics of the campaign, and as there are some here who will be interested with a brief statistical sketch, I will read it as copied from a report of the committee appointed to inquire into army medical organisation:—From the 17th of July, when the first battalions landed at Alexandria, to the 9th of October, the date upon which the force ceased to be considered an army in the field, the average strength of the force, including the Europeans of the Indian Contingent, but not the Royal Marines, is shown to have been 13,013 non-commissioned officers and men; the number of admissions to hospitals were 7,590—viz., 378 wounded in action, 7,212 suffering from disease or injuries; the number of deaths returned is 174—74 died of disease, 5 from accident, and of the remaining 93, 82 were killed in action, and 11 died of their wounds subsequently. The admission rate per 1000 was 582·3, and the death-rate 13·21. The number of men invalided to Malta or England was 2,321. Thus, up to the 19th of October, less than 3 per cent. of the wounded men admitted to hospital died; of the remaining 7,212 admitted to hospital, 74 died of disease. There remained under treatment in the hospitals in Egypt on the above date 1,444. The figures give a death-rate for the whole force of 24·39 per 1,000 per annum. Of the officers 10 were killed in action, 52 were wounded or injured, of whom 2 died. What I have now read is ample proof of the skill and attention of the medical officers. There was no pyæmia, no erysipelas, no hospital gangrene, no case of blindness from ophthalmia. Contrast this with Sir James M'Grigor in 1804, when he describes ophthalmia as a plague, 1,604 men of the regiments suffering from the affection, and the final sending home of 1,000 men blind. Seven men only remaining from ophthalmia, none went blind. (Applause.) This is the practical result which follows the scientific knowledge of surgery and its auxiliary branches. That proves the character of the work done by you. When I read for the first time these statistics and the very small mortality it brought me back to my more youthful and collegiate days, when we were wont to read the Iliad of Homer, and as you will remember, at the siege of Troy, Menalaus was wounded, the brother of Agamemnon, this being a great joy to the Trojans, a great dismay to the Greeks; but Agamemnon, equal to the occasion, calls his herald, and with winged speed sends him for the great surgeon Machaon, to whom Homer ascribes the term excellent, and Machaon having drawn out the arrow from the abdomen of the yellow-haired Menalaus; and in passing I may say that Homer mentions three ways in which the Greeks treated wounds: first, "pulling out," secondly, "cutting out," thirdly, "pushing through;" and now that the black pains of Menalaus have ceased, by reason of the sharp hooks of the arrow being removed, Nestor, Agamemnon, and other noble chieftains being in conclave we find the following remarkable statement made after Machaon himself has been wounded: "A warrior surgeon is equivalent or equal to many ordinary fighting men." These words I consider, Sir, peculiarly fitting and appropriate to you respecting the Egyptian campaign.

Surgeon-General Crawford and Surgeon-General Sir James Hanbury having returned thanks for the honour done them, they signed the Roll of Honorary Fellows, and the proceedings terminated.

◆

We are asked to announce that H.R.H. the Prince of Wales has consented to become Vice-Patron to the Royal Hospital for Diseases of the Chest, City Road. The receipts of the public festival at which the Prince of Wales presided on the 1st June have reached the sum of £5,082.

The Académie de Médecine has received £25,000f. from a M. and Mme. Victor Saint-Paul, which is to be awarded to any one, no matter of what nationality or profession, who shall discover a cure for diphtheria which the Academy shall recognise as efficacious and certain. Until the prize is actually awarded the Academy will spend the interest by awarding every two years a prize to the investigator whose labours in regard to diphtheria shall seem to deserve it best.

WEDNESDAY, JULY 25, 1883.

PRECAUTIONS AGAINST CHOLERA.

SINCE 1873 until the present occasion Egypt has remained free from cholera. When, therefore, about a month ago the disease made its appearance in Damietta, the question naturally occurs, Was the condition of that place, as regards "sanitation" or otherwise, in any respect worse than it had been during that long period of freedom from that disease? There is no information that such was the case. From Damietta the disease extended along the line of river and railway in one direction; on the other hand, places between which no direct communication of either kind exists have been attacked in succession. Up to the present time the general track of the epidemic has been in one direction only, notwithstanding that means of communication were at the outbreak of the disease quite as great, if not indeed greater, in other directions than in that selected by the malady. But although, up to the present time, cholera seems to be advancing along a line away from Europe, experience of past epidemics supplies many instances in which the disease has "doubled back" upon itself, so to speak; therefore, instead of indulging in prophecies that it will not visit England, the clear duty of all concerned is to prepare for it as if its recurrence in this country were certain. Taking this view of the subject, the Local Government Board has issued a series of instructions, some of which are excellent in themselves at all times, whether cholera is expected or not; but others are no more certain to be carried out now than they were at any time in the past, or to be effectual, even were they carried out, in preventing the occurrence of cholera in particular localities. Numbers of such localities exist; their position is perfectly well known; they have hitherto been "hotbeds" of epidemic diseases of different kinds; and, as in the past, so they may be expected to be while their own physical conditions remain as they are—their population in crowded habitations, poor, badly fed and clothed, drunken in habits, and more or less degraded by crime.

It is no doubt a highly commendable state of things to have good water, good sewers, clean privies, and tidy houses; but how can the great mass of the poor, living under such circumstances as these, be expected to suddenly effect improvements in these respects, the greater number of which are really out of their own keeping? Why is it, also, that if these conditions, as they now exist, are the cause of cholera, that disease has not prevailed in such places for years back? If, as is stated, the cholera of 1866 arose from defective water supply—and there is even now no certainty that in this respect an improvement has taken place, while in the interim cholera has for a number of consecutive years been absent—the fact is obvious that the defect alluded to is of itself insufficient for the causation of cholera.

The purport of the Memorandum by the Local Government Boord is altogether conditional. Thus, according to that document, it is *possible* that cases of cholera may be brought into ports in this country. The measures prescribed by the Board in July, 1873, confer powers so as to prevent as far as *possible* the spread of the disease, in order that local populations may make their self-defence as effective *as they can*. Further instructions are given. Thus, cholera is a *little* contagious, in the sense that small-pox and scarlatina are contagious; yet it has an infectiveness of its own—namely, through discharges from subjects of the disease. Accordingly, minute instructions are laid down with a view to prevent the propagation of the disease by means of those discharges. Granting, however, that the disease when it has assumed the characters of an epidemic may be conveyed to individuals in the way indicated, the sphere to which it can so extend is limited as compared with that over which epidemics prevail in the absence of any possible propagation of this kind. Under any circumstances, the instructions now issued will do good in respect to personal comfort and convenience if only they are carried out. But that is all we have any just grounds to expect they can or will do.

◆

HONOURS FOR MEDICAL MEN.

THE popular and professional excitement which has attended the recent conferring of a knighthood on a distinguished Dublin surgeon has evoked a good deal of discussion as to the anomalous position in which men of science generally are placed as regards honorary distinctions. It would seem indeed that there exists no titular decoration which can be fittingly conferred on great physicians, surgeons, or scientists in recognition of their attainments and eminence. Life peerages which have been occasionally given to lawyers of the highest rank have never, on any occasion, been granted to medical men or to scientists, and we admit that an honour of this degree would not meet the want of a titular distinction for our profession. Lawyers have usually received peerages as much because of the necessity having arisen to reinforce the Law Lords of the Upper House as for their personal merits; but the same reason does not exist for co-opting a physician, surgeon, or scientist, and we imagine that if precedent were broken by the election of a doctor-lord, the medicl peer would feel himself rather out of place in the "gilded chamber."

The life peerage being unattainable or undesirable, there remains no distinction at Her Majesty's disposal other than knighthood or baronetcy. As regards the former title it has a certain suitability to the case of a scientific man, because of its being a decoration personal to himself and not hereditary, but it is utterly wanting in the prestige which a decoration fit for the *élite* of our profession should possess. It has been, heretofore, the reward of respectability and of commercial success, rather than the recognition of genius or of industry devoted to the public welfare. It is quite right that the grant of knighthood to a popular Lord Mayor should mark some special occasion or ceremonial, but it is equally clear that a distinction used for that purpose cannot be fittingly offered to, and will not be thankfully accepted by, a man who has spent a life of industry and thought in advancing the science to which he is devoted. Nothing then remains for such a public benefactor but the distinction of baronetcy, which, however, is beyond the reach of all but a few, and is furthermore encumbered by its hereditaryism and by the necessity for providing a handsome independence for the successive heirs of the title. Out of twenty scientists who might fully deserve titular recognition of their eminence not more than one or two would be found who could afford to settle an independent income on their eldest sons, and this being, we believe, insisted on by Her Majesty as a qualification for baronetcy, the great majority of those deserving of the decoration are thereby excluded from it. There is, indeed, no reason why the testimony which the Soverign bears to the special eminence of a subject should descend to the son, who may be anything but eminent or deserving of notice, and certainly our experience of the succession to Irish medical baronetcies affords on the whole strong reason against the adoption of an hereditary title as a proof of scientific worth. We hope, therefore, that the Queen's advisers will at some future time take the subject of titular distinctions for scientific men into consideration with a view to establish some decoration suitable for their claims. The title of K.C.B. would exactly meet the necessities of the case, and there is precedent for granting it to scientific men, and we would venture to suggest the custom which usually restricts that honor to civil servants and military officers should be abrogated in favour of meritorious members of our profession, and other men of scientific eminence.

We do not at all infer that baronetcy should not still be granted in special cases, but we urge that, as it does not meet the circumstances of the great majority of those who deserve a title, some life title should be substituted for it. It is quite certain, at least, that physicians and surgeons of high rank will not consent to share the honour of knighthood with the estimable commercial men and civil dignitaries upon whom it is usually conferred.

◆

AMATEUR DOCTORING.

The trial of the Rev. Mr. Timmins, vicar of West Malling, in Kent, on a charge of manslaughter, took place last week, during the Maidstone Assizes, before Mr. Justice Day, and resulted in a verdict of acquittal. The circumstances of the case were reported by us at the time of their occurrence, and were briefly as follows: A young female parishioner of Mr. Timmins', who was in a low consumptive state, was taken in hand by the vicar with a view to improving her health under his efforts at doctoring. The reverend gentleman was in the habit of proffering such aid to his dependents; and it was claimed for him that, in virtue of having attended a course of lectures at St. Thomas's Hospital some forty years ago, he was qualified to indulge a passion for therapeutical philanthropy. For the case in question his prescription took the somewhat unusual form of essential oil of bitter almonds, the effect of which was not unnaturally to cause the death of the unfortunate patient, and thereby lead to the accusation from which Mr. Timmins has just been relieved. There has, of course, been no suggestion throughout of the existence of any but the most amiable and kindly motive on the part of the clergyman; his only desire was to give relief to a suffering member of his flock, and the gravest charge against him has been a want of discretion in relying too securely on the reality of knowledge gained by a brief and antiquated experience of medical lectures. The incident, however, very properly suggests an important reflection as to the limits which should be imposed on such proceedings as those which in Mr. Timmins' case led up to so melancholy a result. It has been urged, with no little show of justice, that the clergyman of a country village, for instance, should not be debarred from indulging a taste for amateur doctoring, because of the frequent inability in such places of obtaining qualified medical assistance. We may, however, safely assume that the most liberal apologists in this direction would hesitate to open the materia medica indiscriminately to clerical enthusiasts in medicine; and that they would, at any rate, prohibit the employment by them of the more poisonous drugs, the administration of which can never be safely entrusted to other than skilled hands. Moreover, it must always be insisted that so long as the attendance or advice of a regular practitioner is easily to be secured, *no* interference, either from clerical or lay amateurs, can be justified, especially in cases where the nature of the disease is of a kind to excite suspicions of gravity.

At West Malling there is not the excuse of an absence of medical men, for we learn that a surgeon was called to see the deceased immediately that it became apparent she was *in extremis;* and obviously his services had previously been at least as easily obtainable as those of the vicar. We are so accustomed to hear of cases in which the gratuitous, and often enough distasteful, meddling of clergymen with the physical ailments of their parishioners is complained of, that there is no impropriety in observing that it is excusable only in situations where a little timely common sense and calm judgment can avail to tide over an emergency until the arrival of medical aid. The practice of *prescribing* is at once objectionable and eminently unsafe. It needs an apprenticeship and experience to enable a man to give a remedy for even the simplest ailment; and it is little less than weakness in our laws which permits the administration of *any* medicine by persons who are not qualified by education and registration to take on themselves the responsibility attaching to the duty.

In the particular case which has given rise to these remarks the kindness of feeling which instigated Mr. Timmins' officious interference is unquestionable, and the jury entrusted with a decision as to the offence committed have given full weight to the motives which influenced him; but it will be well indeed if likeminded clergymen with the accused vicar will take well to heart the emphatic condemnation of Mr. Justice Day, who most strongly disapproved of a clergyman or any other person taking on himself to give medical advice in cases of serious illness. So long as the practice is indulged in, such accidents as that giving rise to the late trial will most certainly occur; and the result can scarcely be always similar to that just experienced. No one, we feel sure, more keenly regrets the painful conseqence of his act than the author of the misfortune; and he may well be grateful if the pain of mind he has undergone should deter other of his brethren from following in the path he has himself pursued with such lamentable consequences.

◆

Notes on Current Topics.

Smoke Abatement.

Whether the next generation of Londoners will be entirely relieved from the smoke nuisance suffered by existing residents in the metropolis or not, there can be no question that they will enjoy a very much improved atmosphere as compared with that inhaled in and about the city to-day. So much as can possibly be done by individuals and societies in the way of abating the great smoke worry will assuredly be done; and already it is evident that some good has been accomplished as a result of the recent agitation *contra fumos*. At a meeting held on Monday, the 10th inst., at the Mansion House, the Lord Mayor presiding, it was reported that since the Smoke Abatement Exhibition at South Kensington the public had shown a desire to aid in the movement by employment of improved stoves and fuel such as coke, smokeless coal, and gas. The Council of the Society have carefully inquired concerning the extent of such manifestations of anxiety on the part of the general public, and they express a decided satisfaction at the proofs they have received of a widespread feeling in favour of the principles of the Association. A practical outcome of the meeting on Monday is the establishment of the Smoke Abatement Institution, definitely created to carry out three objects dwelt upon by the Duke of Westminster—viz., the formation of a permanent exhibition of improvements in grates and approved apparatus for assisting smoke abatement; the foundation of a permanent laboratory and workshop, where new inventions may be tested and inventors find facilities for perfecting their conceptions; and the provision of lecture halls and reading rooms for public lectures and discussions, &c., on matters dealing with the subject of smoke abatement. In fulfilment of this programme contributions have been promised, from the Duke of Westminster £500, and Messrs. Waring and Cubitt, each £100.

Farewell Dinner to Professor Macalister, M.D., F.R.S.

Several of the medical and scientific friends of Professor Macalister entertained that gentleman on Tuesday, the 17th inst., at a complimentary dinner at the Shelbourne Hotel in Dublin, prior to his departure to take up the duties of the Chair of Anatomy in the University of Cambridge, to which he has recently been appointed. The Rev. Dr. Haughton occupied the chair, and Mr. Wheeler, President of the Royal College of Surgeons, was vice-chairman. Nearly all the members of the staff of the Medical School of Trinity College were present, and the various educational and scientific institutions with which Dr. Macalister has been connected in Dublin were well represented. In consequence of absence from Dublin, or unavoidable causes, Drs. Robert McDonnell, Mapother, Percival Wright, Franks, and many other friends were prevented from assisting. Amongst those who took part were Sir J. Lentaigne, President, Royal Zoological Society; Dr. Banks, Regius Professor of Physic; Dr. Moffet, President, Queen's College, Galway; Professors Bennett, Purser, Finny, Reynolds, Kirkpatrick, and Walter Smith; Drs. J. Little, T. E. Little, Sigerson, Ball, C. Nixon, Frazer, Benson, R. Hayes, Hepburn, Barton, W. Wright, Knott, Denham, Barrington, Brooks; Rev. Maxwell Close, Treasurer, Royal Irish Academy; Mr. Archer, F.R.S., Hon. Secretary, Microscopic Club; Mr. Manly, Mr. Maxwell Hutton, and Mr. P. S. Abraham, Hon. Secretary, Biological Club, who acted as Hon. Secretary. The dinner was of a *recherché* character, and after the toast of the evening, "Our Guest," which was spoken to by the chairman, the vice-chairman, the Rev. Maxwell Close, and Sir John Lentaigne, the proceedings were varied by some songs rendered by Dr. Hayes, Mr. Abraham, and others.

London Water Supply.

An analysis of the results of examination of 2,110 samples of drinking water supplied by the various London companies during 1882 is contained in the annual report of Drs. Odling and Tidy and Mr. Crookes, and submitted to the Local Government Board. The general tenour of the report is favourable to the fluid supplied, that of the New River Company being the water showing the most invariable excellence as judged by clearness, brightness, and freedom from suspended impurities. To grumbling ratepayers the report will probably be consolatory; but too much satisfaction should not be permitted in respect of it, for although the average amount of organic matter contained in the water supplied to the metropolis is no more than 1·5 per million, yet the exact nature of this small residue is the standard of its virulence; and on that it is not possible for chemists to afford any information of value. So long as the minutest trace of organised matter is present, in active form, in drinking water, so long is it a dangerous, and possibly deadly, beverage. Until, therefore, a process has been devised for ridding such water of its animal impurities *completely* we must be content to feel grateful for the comparative purity of the waters we drink on the certificate of Mr. Crookes and Drs. Odling and Tidy.

Telephones for Hospitals.

We are glad to learn that the system of hospital intercommunication by telephone is rapidly extending in Dublin. Since our last issue the Mater Misericordiæ Hospital has "joined up" to the Central Exchange. The governors of the Richmond Hospital have given the order for connecting the hospital and the whole surgical staff also with the Exchange; and we understand that, within a few weeks, it is probable that the Meath Hospital and Co. Dublin Infirmary will have also been connected by wire with its surgical staff. Five of the Dublin hospitals will then be in intercommunication with their surgical staffs; and we hope to be able before long to record that other similar institutions have established the same connections. Stevens's Hospital and the Coombe Lying-in Hospital being situated at the furthest distance from the residences of their surgeons, ought to be the first to establish this communication. The Dublin Orthopædic Hospital is already connected with its chief surgeon, Dr. Swan—not through the Telephone Exchange, but by private wire. The King and Queen's College of Physicians is also in communication; and we hope before long to be able to say that the College of Surgeons has followed suit for the convenience and advantage of Examiners, Professors, Councillors, and Fellows who frequent the College. It would be an obvious advantage to the College as well as its *habitués* if the institution was in communication with the Dublin hospitals.

Parturition among the Maoris.

Mr. F. Hope Lewis, M.R.C.S., who, as resident medical officer in a Maori district of New Zealand, has had ample opportunity of becoming acquainted with the habits and customs of the native inhabitants, has sent a letter to the *Australian Medical Gazette*, wherein he corrects previous mis-statements by other observers in respect to the *modus operandi* of the Maori women during labour. Mr. Lewis thus describes the course of events:—When the woman is taken in labour, she, with one or two of the same sex, goes into the titree or manuka scrub some two hundred yards or so from the dwelling, and if the weather is bad, a tent or "breakwind" is erected, according to the circumstances of the family. In fine weather no preparation is made. They are never confined in their own huts. The posture during labour is the kneeling one; the woman clasping her arms around one of the attendants who supports and presses the abdomen, while the other receives the child at birth from behind. The placenta is removed by pressure on the womb through the abdominal wall, and if there is any difficulty the woman goes at once into the cold or tepid water, and by kneading the womb as above described the object is attained. In cases where time and pressure do not effect delivery the woman is permitted to die, no internal operations being known among the natives.

A New Convalescent Home for Dublin.

For some time past Lady Napier has been endeavouring to obtain a site in the vicinity of Dublin for the erection of a convalescent home to the memory of her sons. Owing to the difficulty of obtaining a suitable one, the project was modified from time to time; and finally an arrangement was entered into according to which Lady Napier was to make an endowed addition to the Convalescent Home at Stillorgan. The trustees of the latter having previously determined to improve the Home, the two schemes were very advantageously combined. The many difficulties imposed by the imperfect and straggling character of the old buildings, as well as by the desirability of unity of effect, stood in the way of a very rigorous application of the most advanced views. The necessity of single rooms, in addition to the small wards, and the relative purity of the general atmosphere of convalescent hospitals, render an improved corridor system the only practicable one for small numbers. The aspect of the Napier addition is to be south-western, and a tower containing the sanitary arrangements is to be placed to the north-east, connected by open passages to the main building, the wards and day-rooms of the latter having no windows on this side. The old buildings lie further to the north-east, and are to be considerably improved. The designs for the much-needed work and efficient preventive of relapse have just been completed by Messrs. Carroll and Pentland, architects and engineers, and the works are to be proceeded with immediately.

Humanum est Errare.

Some few weeks ago Dr. Comegy, of Cincinnati, in the United States, had under his care a case which he considered to be, and described as purpura hæmorrhagica. The patient died, and was subsequently despatched, presumably for burial, to a distant town, where the relatives opened the coffin against orders and contracted *small-pox*. Dr. Comegy had mistaken for purpura hæmorrhagica a case of *purpura variolosa*, and had erred, moreover, in company with a physician to a small-pox hospital, who had also been called in consultation on the case. It is not difficult to understand that when these facts became known the lay press were emphatic in denouncing professional ignorance; nor we imagine is it peculiarly American usage for competing doctors to take advantage of such a mishap, as was done by certain of Dr. Comegy's professional brethren. The more respectable members, however, supported him manfully; and two highly respected and well-known physicians went the length of publishing a letter to their fellow practitioner, wherein they avowed themselves to have made a similar mistake in 1876, in a case reported to the *Cincinnati Clinic*. This proof of fellowship and *esprit de corps* is a grateful indication of true and right feeling, and is honourable alike to Dr. Comegy, and to his supporters, Drs. J. T. Whittaker, and P. S. Connor. Curiously enough, a second similar case is now mentioned as having occurred in the same town a week or two after Dr. Comegy's, the self same diagnosis, purpura hæmorrhagica, being arrived at in this also, the attendant being another physician in large practice named Dr. Conroy. In this instance a coroner's inquiry was called for by the Registrar, and on post-mortem examination purpura variolosa was discovered.

The Army Medical Department.

It is obvious that a turning point in the "reorganisation" of the Army Medical Department has at last been reached, and that further changes hinted at are to be in a direction "back again." The discussion initiated by Lord Bury in the House of Lords points to a re-introduction, although in a modified form, of the regimental system as regards medical officers. There are many who look upon the station hospital system as really the chief cause of the break-down now acknowledged to have taken place in Egypt, and who will regret that it is to be persisted in yet a little longer. Others—and they the medical officers who are most concerned in the matter—will regret to read what his Royal Highness the Duke of Cambridge said on the subject of that long vexed question—combatants and non-combatants.

Fly Papers.

In Prussia the sale of poisonous and arsenical fly papers is only permitted to chemists and those who are authorised to deal in poisons. Such persons even are only permitted to sell them under the same regulations as must be observed in the sale of all poisons. These regulations require that a poison certificate be given with them, and also that the word "poisonous" be stamped on them.

American Medical Association.

The thirty-fourth annual meeting of this Association was held at Cleveland, Ohio, on June 5th, 6th, 7th, and 8th. Among the business transacted was the adoption of a resolution providing for the appointment of a committee of five to press upon Congress the desirability of securing better medical attendance on ocean steamers. It was decided to hold the next meeting in Washington, on the first Tuesday in May, 1884, and following days.

Lacombe, the French wholesale druggist who was accused of fraudulently substituting sulphate of cinchonidine for sulphate of quinine, which he supplied to the Paris hospitals last autumn, has been sentenced to a year's imprisonment and 50 francs penalty, and is also called upon to pay for the advertisement of the judgment in a dozen French journals.

A curious instance of fear of being "buried alive" has just been brought to notice by the proving of the will of Major Andrew Gammell. This gentleman deposed that a sum of one hundred guineas, free of legacy duty, should be paid to Mr. Barnard Holt, F.R.C.S., or failing him, some equally eminent surgeon, as a fee for surgical examination of his body after death.

The Contagious Diseases Acts.

Captain Price last week asked Mr. Gladstone whether, after the statement as to the alarming increase in the number of cases of contagious disease in Her Majesty's forces since the abolition of compulsory examination, he still adhered to his intention of endeavouring to pass this session a Bill for the repeal of the Contagious Diseases Acts.—Mr. Gladstone said the Government must take some further time to consider, with respect to three Bills of importance, whether they would ask the House to proceed with them or not, and he could not give any further intimation of the intentions of the Government with respect to these three Bills until they got through Committee on the Corrupt Practices Bill, and made great progress in Committee on the Tenants' Compensation Bill.—Mr. Puleston asked whether, in view of the alarming character of the information which had been given to the House, the Prime Minister intended to proceed with such a Bill.—Mr. Gladstone said it did not lead him to vary the answer he had already given.

A Central Local Government Ministry.

Sir A. Gordon has given notice that on the motion for the second reading of the Local Government Bill for Scotland, he proposes to submit a resolution in favour of the reconstitution of the Local Government Board for England as a Local Government Board for Great Britain, with a separate branch for each country, and its representation by a Cabinet minister.

Foreign Charlatans.

We are acquainted here in France (*Gazette Hebdomadaire*) with the American quack high in colour, loud in voice, noisy and impudent; with the Spanish charlatan, mystic, sombre, the crucifix in hand, always ready in prayer; with the paternal Dutch impostor, writing his consultations with a flask of urine in hand, as in the famous "Dropsical Woman" of Gerard Dow. But the German charlatan is of a different species; he is surrounded with piles and electric apparatus; he is a professor of occult physical science, who cures with the same spark pulmonary tuberculosis and cerebral debility. He is a professor, a distinguished lecturer, the apostle of a newly-discovered art. The Medical Society of Leipsic are about to take measures against two such individuals, one an ex-carpet-worker, now director of an electro-therapic establishment, and another, Hindorf, a professor of natural medicine.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Cardiff 9; Edinburgh, Halifax, Birkenhead, Plymouth 13; Norwich, Bradford 15; Leicester, Derby, Blackburn, Bristol 16; Leeds, Salford, Portsmouth, Bolton 17; Oldham, Brighton 18; Nottingham, Birmingham, Hull 19; Dublin, Sheffield 20; Wolverhampton 21; London 22; Glasgow, Liverpool 23; Preston 24; Manchester, Huddersfield 25; Newcastle-on-Tyne 27; Sunderland, 96. In this return, as relates to Sunderland, the victims of the catastrophe whereby more than two hundred children lost their lives at an entertainment are included.

Society for Relief of Widows and Orphans of Medical Men.

At the last quarterly court of directors of this Society, Sir George Burrows, Bart., President, in the chair, four new members were elected, the deaths of four were reported, and two other gentlemen had ceased to be members. A sum of £1,207 was distributed among fifty-seven widows and twenty-eight orphans. The death of one widow receiving a grant of £50 per annum was reported. There were no fresh applications for grants. The expenses of the quarter amounted to £71 13s., including an honorarium of 25 guineas to Mr. Blackett, in recognition of heavy additional services rendered to the Society, of which he was re-elected Secretary.

Fees for Post-mortem Examinations.

In the House of Commons on Thursday, the 12th inst., Mr. O'Brien put the question as to whether, at the recent assizes, the Longford grand jury disallowed the fee of the doctor who performed the post-mortem examination at the request of the county coroner on a pauper who died in the Granard workhouse, and that the judge summarily sanctioned the disallowance, remarking, "The money (£1 1s) is not worth scuffling about;" whether the doctor was specially called in by the coroner instead of the union medical officer in consequence of the death having taken place in the workhouse, and whether this gentleman was to have no remuneration for services performed at the request of the proper authority because the grand jury chose to disallow his fee and the judge did not think the amount worth discussion.—Mr. Trevelyan: It is the fact that the grand jury of Longford, after a careful investigation, disallowed medical fees recommended by the coroner, and amounting to five guineas; and, as to one guinea of the five, the ruling of the grand jury was brought before the judge for review. The grand jury thought that the evidence of the union medical officer was sufficient. His Lordship thought so too, and declined to interfere in such a matter, as he was perfectly entitled to do.

With great respect to the judge and grand jury, the charge for a fee to a medical witness outside the workhouse is perfectly legal, and it could be recovered, without doubt, by suing the coroner. It has been decided long ago by Chief Baron Pigott, Baron Fitzgerald, and Mr. Justice O'Brien that the coroner may hold an inquest and pay a fee to any witness he pleases, and, whether he is right or wrong in so doing, the grand jury must recoup him, if he acted *bona fide* in the matter. This law was laid down in Mr. Justice O'Brien's charge to the County Dublin Grand Jury on April 16th, 1862.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Madras 31, Paris 23, Geneva 23, Brussels 24, Amsterdam 23, Rotterdam 19, The Hague 28, Copenhagen 29, Stockholm 21, Christiania 14, St. Petersburg 31, Berlin 39, Hamburg 21, Dresden 26, Breslau 45, Munich 36, Vienna 27, Prague 37, Buda-Pesth 37, Trieste 22, Rome 23, Turin 23, Venice 22, Lisbon 27, New York 25, Brooklyn 20, Philadelphia 17, Baltimore 19.

"British Otological Society."

A movement has been set going for the formation of a special society for the consideration of all subjects connected with the ear, nose, and pharynx (normal and pathological), and to promote an interchange of ideas amongst those interested in these subjects. The society is to meet in London three (or four) times a year, and the meetings are to be followed by a dinner. The subscription is to be 10s. 6d. annually, each dinner being paid for separately. The council is to consist of one London councillor for every five London members of the society, and of one provincial councillor for every five members residing outside the London district. The hon. secs. *pro tem.* are Dr. Urban Pritchard and Dr. Cresswell Baber.

The Diagnosis of Typhus.

An outbreak of typhus fever among the inmates of Nazareth House, Hammersmith, a charitable institution superintended by sisters of charity, forms the subject of a report to the Local Government Board by Mr. John Spear, who made an official inspection of the establishment. This, which provides support for 133 old people of both sexes, and 175 children, aged from a few months to 16 years, is conducted by 57 sisters of charity under a mother and assistant mother. Typhus fever broke out among the children first and extended from them to the sisters of charity who were in charge of them as nurses, but it is interesting to learn that the latter succumbed only after long and arduous exertions and continued fatigue, which, as is well recognised, is a potent predisposing influence in typhus. Mr. Spear shows very conclusively how the disease was introduced from without by means of one of the children's visitors consisting of an adult man and his child three years old, who had been living in a cellar dwelling, and were convalescent from some kind of fever at the time of visiting Nazareth House. As a result of careful inquiry and examination Mr. Spear arrived at the conclusion that the spread of the disease was not attributable in any sense either to overcrowding or dirt, but that it extended because, occurring at first in a mild form amongst children, the disease remained for some three months unrecognised, the sick, the convalescent, and the healthy mixing together. This difficulty of appreciating the existence of so serious a complaint for so long a time, resting on the authority of so undoubted an observer, deserves to be carefully borne in mind, the more especially as it was experienced by the medical attendants at the house, who failed to grasp the real importance of the condition of the inmates. Typhus is at once so serious a fever, and so easily generated in every populous and indigent quarter of a great city that we cannot be too keenly alive to all the phases it may assume; and as a new addition to its natural history Mr. Spear's report is of very considerable value.

Acting on suggestions made to them the Local Government authorities have arranged for the publication of certain of the reports presented to the Board by its medical officers; such as are issued in this way can, therefore, be purchased at the printers, and by this means a most valuable series of investigations will be accessible to the profession generally.

At a recent meeting of Convocation of the Royal University, Lord O'Hagan presiding, Dr. Arthur Hill Curtis was elected a representative of Convocation on the Senate of the University for the ensuing three years.

The rates of mortality throughout the United Kingdom continue very low, especially from diseases of the zymotic class. Last week the highest annual death-rates from measles were 1·9 in Brighton, 2·2 in Salford, and 3·1 in Newcastle-upon-Tyne; from scarlet fever, 1·1 in Manchester and 1·3 in Birmingham; from "fever," 1·2 in Derby and in Huddersfield, 1·4 in Halifax, and 2·0 in Portsmouth; and from diarrhœa, 3·4 in Bolton, 3 7 in Preston, 4·3 in London, and 4·4 in Leicester. The 41 deaths from diphtheria in the large towns included 26 in London and 5 in Glasgow. Small-pox caused but one death in the large towns: this fatal case occurred in Newcastle-upon-Tyne.

◆

Scotland.

[From our Northern Correspondents.]

The Closing of the Extra-Mural School.—This school closed last Friday, when the prizes were given by the several lecturers. The Practical Chemistry Class at Minto House has greatly increased. The Anatomy Class at the same school was larger than that in the University. There has been a break-up of the Marshall Street School, Mr. Drinkwater, who lectured there on chemistry, having gone to other quarters. It is very generally felt that the position of the Extra-Mural School has been injured by the action it has taken in siding with the Corporations. The school has claims which cannot be ignored by the Government: the Corporations have none. When the Corporations found that their hour of dissolution was at hand, they have not scrupled to use the school which they had persistently for years ignored to save them. By attempting to save the doomed colleges, the school has weakened itself, without improving the prospects of the colleges. The business has all along been managed by the small portion of the school located at Surgeons' Hall. The suicidal action of the school is greatly enjoyed by the University, who now see that the fate of the one is the fate of the other.

Health of Edinburgh.—The mortality in Edinburgh for the week ending with Saturday, the 14th inst., was 58, and the death-rate 13 per 1,000. Diseases of the chest accounted for 34 deaths, and zymotic causes for 8, of which 2 were due to fever and 4 to measles, the intimations of these diseases for the week being 6 and 85.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 14th inst., were at the rate of 24 per 1,000 per annum, against 28 in the preceding week, and 22, 20, and 22 in the corresponding periods of 1882, 1881, and 1880.

Sudden Death of Dr. Houston, of Kirkcaldy.—Much regret is felt all over the Kirkcaldy district at the sudden death of Dr. Patrick Houston. Deceased was visiting his patients up to Saturday week at midday. Immediately after symptoms of peritonitis set in, from which he slightly rallied on Sunday morning, but became worse towards evening, and died on Monday morning. Dr. Houston, twelve years ago, succeeded the late Dr. Stoddart, and from the very first enjoyed a large practice. As an experienced and trustworthy family doctor he was very highly esteemed. The prospect of a long and useful life seemed before him, but he has died in the midst of his days, a comparatively young man. The deceased was about 50 years of age, and leaves a wife and seven children—one son and six daughters, the eldest thirteen, and the youngest three years of age.

Literature.

THE MINERAL WATERS OF EUROPE. (a)

When one day there comes to be written, from the standpoint of modern science, a history of human superstition, those chapters of the work which deal with belief in the various virtues from time to time accredited to waters, either of miraculous or of natural origin, will assuredly not be either the shortest or the least interesting. No one who has visited one of the springs which occur in almost every rocky range from the Grampians to the Pyrenees, and which a ready faith invests with supernatural curative power, can see much reason to expect that such belief will suffer measurable diminution for many generations. With the mineral spring proper the case is different; and while it seems long to look back to the time when the temples to Esculapius were erected near to such sources, and it is true that even to-day much mysticism is allowed to surround the subject, the chemist of the age is in a position to assert that the curative action of any given mineral water is a result of the combined therapeutic action of the sum of its constituents. The book before us bears ample testimony to this view, for it is the joint work of an able chemist who has not only collated and commented upon existing analyses, but has in many instances supplemented them by new ones; and of a physician of skill and experience who has used these analyses as a basis of therapeutic application. One of our authors does indeed, in his introduction, express an opinion that the more complicated spas cannot be imitated artificially. We quote this as illustrating the sometimes pertinacious adherence of the shreds of a cast-off belief. For it is impossible to logically admit that the synthetic faculty which enables the chemist to build up from its component atoms a molecule of salicylic acid or alizarin, deserts him when he is confronted with the problem of imitating a watery solution—complex though it be – of salts and gases. It would be perhaps nearer the truth to say that no chemist has yet found it worth while to do so.

The plan of the book has been well conceived and carefully carried out. The different waters are first of all classified under the following heads:—Purgative, Alkaline, Arsenical, Table, Chalybeate, and Sulphur. Each of these classes has a chapter devoted to its chemistry and a chapter to its therapeutics. The authors point out that as their work has been confined to the waters which reach these countries in bottle, all considerations of climate, change of air and scene are eliminated, and that with these—in many cases new—analyses before him, the physician prescribing a mineral water, will look upon it as he would any other weapon in his medical armoury. This is distinctly as it should be, and if the whole subject be viewed in the clear light of this and other insignificant passages in the book, any tendency to envelope it in mysticism will have received a wholesome check.

Of table waters for example we read, "The marvellous qualities attributed to some of the ingredients met with in minute quantities (mere traces) serve to amuse the credulous, and sometimes the presence of these substances induces people to replace injurious fluids by these innocent waters." There is a quiet satire too in the observation that numerous "holy wells" that have lost their popularity also furnish excellent "table waters," which is amusing.

More seriously useful, however, is the warning conveyed in the statement that "many of the most famous sulphurated (*sic*) waters are little else than indifferent ones with a flavour of sulphuretted hydrogen."

(a) "The Mineral Waters of Europe: including a short description of Artificial Mineral Waters." By C. R. C. Tichborne, LL.D., F.C.S., M.R.I.A., and Prosser James, M.D., M.R.C.P. London: Baillière Tindall, and Cox. 1883.

There are few pages of the book that do not contain some fact either instructive or suggestive. It is pointed out, for example, that not only were many of the old analyses "specially selected" by the proprietors of the springs, but that the springs themselves are subject to change in their chemical composition. A curious example of this may be found on page 33, where an analysis of the authors' is contrasted with one by Liebig. Liebig's figures show the solid contents of a gallon of the water to be 1,912 grains, while Dr. Tichborne's analysis gives 3,079 grains. If comment upon such a discrepancy be desired it will be best found in a quotation from Sir H. Thompson which is given at full length in the context. Various analyses of Pullna water present discordances no less striking. (Pp 34-35.) Nor must it be forgotten that in some cases the loss of carbonic acid in the process of bottling may conduce to change in the composition of waters.

Moreover, it is broadly hinted that such a process as "strengthening" a natural mineral water by a judicious addition of some lacking ingredient is not altogether unknown to the proprietors of springs. In the case of one well-known water such an addition would indeed seem to be openly avowed. It is distinctly stated, too, that Selters water is dosed with sodium chloride, avowedly with the object of precipitating part of its iron. It is remarkable, not only that the analysts have not long ago found this out for themselves, but that neither the clever author of "Bubbles from the Brunnens," nor the late Dr. Aldridge, both of whom witnessed and graphically described the process of Selters bottling, allude to such addition. The former writer does indeed say that the water drunk at the source has a chalybeate taste, not noticeable in the bottled water.

New analytical methods, too, must be credited with some share in new views as to constitution. The indications afforded by the careful use of *phenol-phthalein*, and particularly those of the spectroscope, may be instanced. The presence of *lithium* in both Schwalheim and Carlsbad waters, first noticed by Dr. Tichborne, is of course a direct result of the application of Kirchoff's great physical legacy to chemistry.

There are in the chemical section of the book few omissions of any real importance to be noted, for on the whole the work has been done admirably well. We do not, however, find any analysis of the best known imported Vichy water—the Celestins—and could have wished to see those of the Lisdoonvarna and Lucan springs. These, however, have not yet been bottled. No less meed of praise is due to the therapeutic portions of the work. Lucidly written and abounding in suggestion, they deal with the action of mineral waters from a thoroughly practical point of view. We regret that our space will not permit us to dwell at any length on details, but we may call attention to the passages which deal with the action of adjuvants in increasing the action of purgative salts, and on that of simple carbonic acid water as an aperient.

We may say in conclusion that no physician who desires either to know the exact composition of the mineral water which he is prescribing, or the indications which point to the selection of some particular source, can afford to be without this compact little volume, the production of which will increase the already well established reputation of its authors, and which has been most creditably brought out by its publishers.

◆

SELECTIONS FROM THE WORKS OF THE LATE J. WARBURTON BEGBIE, M.D., LL.D. (*a*)

This volume has been in our possession for some time, and we must express our regret that it was not sooner noticed. With many of the articles in the work we had been acquainted before they appeared in their present form; but we think the Editor, Dr. Duckworth, has done good service by publishing them in one volume, and that a volume of the Sydenham Society. No more valuable work has been issued by this Society. The memoir of the life of Begbie, with which the volume opens, is one of singular interest, and will be read by everyone with pleasure. He can have been no common man who possessed all the qualities which the Editor describes, even allowing some degree of bias to have crept into the sketch. One thing at least is certain—that Begbie possessed all those points which go to make up a great physician. No one can look over the essays—much less read them closely—without being at once struck with their merit. They are all written by a master hand, and each in turn throws light on the subject of which it treats. We may observe that several of the essays are founded on single cases of disease, but they are scarcely the less interesting on that account, because they are so well selected and detailed. Thus, the essays two, five, and nine are of this kind, the first being a case of acute rheumatism, succeeded by chorea and affection of the heart; the second, "a case of hydrocephalus connected with cancer at the base of the brain;" and the third "a case of fatal croup in the adult, with remarks." These will all well repay perusal, as will also the essays on special medicines, such as turpentine and the muriate of lime. There are no less than four essays on the subject of exophthalmic goitre and heart affection, attended with prominent eyeballs. This number proves the interest the author took in the subject, which, we need scarcely add, is treated most exhaustively, and in the conclusion at which he arrives we are, with our present knowledge, inclined most to agree. He thinks that both the blood is in a deranged condition and that the nervous system, specially connected with the heart, is deranged. The marked anæmia which is so constantly present, and the very excitable state of the heart which also exists, seem strongly to support those views.

It is not our intention to enter into the merits of the several essays which make up this valuable volume. Where all are good no selection could be made. But we may with confidence recommend the work to the special notice of our readers.

◆

NERVE VIBRATION AND EXCITATION AS AGENTS IN THE TREATMENT OF FUNCTIONAL DISORDERS AND ORGANIC DISEASE. (*a*)

The general medical reader is aware that, within the last few years, much attention has been given to the nerves themselves, their special diseases, and treatment; and we believe that considerable advances have been made in the last point more particularly. What is now known as "Massage"—a word for which, we believe, we are indebted to American writers—is one of the ways in which this treatment has been carried out, and that it is a most powerful means for improving the health, in suitable cases, does not to us appear to admit of doubt. Our author, we know, does not consider "massage" and "nerve excitation" as by any means similar. To us they seem the same in principle, though the means for carrying them out are not identical. Both lead to an improved nutrition, and this is, we take it, the main object to be aimed at. It should have been stated that the author believes when nervous tissue acts it is by vibration, just as on the organ of hearing and vision; and that when pain exists this vibration is perverted, and that his "excitation" brings it back to the normal state. Whether these views be literally true remains still to be proved; but they are the views the author holds. We notice that our author enters into a long discussion as to the question of priority of claims on this subject with Dr. Boudet, of Paris. Which was first we will not take on us to determine; but as our author says the Frenchman does not understand his views, the point need not be considered further here. Our author has devised an instrument which at first was worked by a clock apparatus, and subsequently, and with much better result, by electricity. He states that, according to the character of the pain, the vibratory process, of which he describes the mode, is to be modified; that if the pain be a dull, grinding pain, it is to be combated with a high rate of small vibrations; but a very acute pain is to be met with "comparatively slow and large vibrations." We observe that some of the apparatus used is in the form of a brush, and reddens the skin when used (p. 59). Now this fact brings the author's ideas very close to the views of those who advocate the heated iron button for the relief or cure of certain nervous affections; and that this

---

(*a*) "Selections from the Works of the late J. Warburton Begbie, M.D., LL.D." Edited by Dyce Duckworth, M.D. Published for the New Sydenham Society by H. K. Lewis. 1882. Pp. 422.

(*a*) "Nerve Vibration and Excitation as Agents in the Treatment Functional Disorders and Organic Disease." By J. Mortimer Gr ville, M.D. London: J. and A. Churchill. 1883. Pp. 128.

plan existed long before our author had promulgated his own special views is certain. The reddening of the surface by any stimulant frequently relieves nervous pains. But our author deserves credit for drawing more particular attention to the mode of doing it, and to placing the process on a more physiological basis. He shows, too, the advantages, at least in some cases, of using the percenteur at the origin of the nerve, and in others along its course. The author mentions several diseases in which he states benefit, if not cure, results from the use of his plan, such as morbid sensibility of the nerves, the earlier stages of loco-motor ataxy, the improvement of the vaso-motor state, the railway spine, indigestion, constipation, the temporary presence of albumen in the urine or of sugar. As the entire subject is new, we could have wished our author had illustrated his work by detailing a series of cases confirmatory of his remarks. His statements have a kind of vagueness about them which leaves the reader unsatisfied, and which we believe would be removed by a detail of cases. A few cases in which the vaso-motor nerves were impaired and subsequently improved by the author's treatment are given. We would suggest that in the next edition the same should be done for the several affections of which the writer speaks. This, we consider, would be a great improvement to this work, which, however, without these additions, we can strongly recommend to the notice of the profession.

◆

THE STUDENT'S GUIDE TO DENTAL ANATOMY AND SURGERY. (a)

Having reviewed fully the first edition of Mr. Sewill's well-known book, it is unnecessary to do more than notice the appearance of the new edition. The value of this work, which has now been revised and amplified, consists in its completeness, clearness, and conciseness, and it is certainly the best book of the kind both for the practitioner and the student.

◆

THE CHAMBERLENS AND THE MIDWIFERY FORCEPS. (b)

In seeking to know all that may be known of the life, thoughts, and doings of its illustrious dead the world pays rightful homage to those who were its benefactors. We think, therefore, that it was no vain labour to which Dr. Aveling devoted the leisure hours of ten years' professional life in an antiquarian research into the surviving materials which relate to the history of the "Asclepiad" family, memorable as being that amongst which the midwifery forceps was invented and first systematically used. For assuredly no boon to humanity has ever been much greater than this, nor, though the Chamberlens have forfeited much of posterity's gratitude by the mercenary motives which prompted their secrecy in the matter of the forceps, can we on that account withhold from them the credit which is justly theirs for the genius of the conception. Indeed, it appears to us that Dr. Aveling in his preface has properly acquitted the Chamberlens of much of the discredit which has been so constantly fastened on them for having so long and successfully kept their discovery a family secret. "All that can be fairly said against the Chamberlens is that they were no better than their neighbours, and that they failed to recognise the obligation imposed upon all members of our noble profession of publishing freely and immediately any new method of alleviating human suffering which, by their industry or genius, they may have been able to discover."

The outcome of Dr. Aveling's ten years' special research into the records of the Chamberlens is the production of a work replete with interest to every student of obstetrics who takes pleasure in the history of his science. The work, moreover, will do much to enlarge and correct the current accounts of this truly original family, and has, so far as we can now judge, definitely settled the disputed question as to the particular member of the family to whom the credit is due of originating the use of the forceps.

We extract from the work a genealogical tree of those members of the family who possess interest on account of their connection with the history of the forceps.

William Chamberlen.
(French Huguenot Refugee.
Came to Southampton in 1569.)

Peter Chamberlen I.
d. 1631.
(Probable inventor of Forceps.)

Peter Chamberlen II.
b. 1572. d. 1626.

Peter Chamberlen.
b. 1601. d. 1683

Hugh Chamberlen.
b. 1630? d. in Holland.

Paul Chamberlen.
b. 1635. d. 1717.
(Sold secret of Forceps to Roonhuysen.)

John Chamberlen.

Hugh Chamberlen.
b. 1664. d. 1728.

Such information as Dr. Aveling has been able to acquire regarding each of these in the course of laborious investigation has been carefully sifted and set forth chronologically in the pages of his work. Quite apart from the individual interest which attaches to the history of the Chamberlens themselves, the reader will in these biographical sketches find much incidental information concerning the customs and history of the times in which they lived. The limits of a short notice such as this prevent us, however, from attempting to give, even in outline, the various facts narrated, and now for the first time brought to light. Indeed, the narrative would necessarily lose much of its peculiar interest by any such process of condensation.

Having laid before his readers a narrative of the history of the Chamberlens, Dr. Aveling brings his work to a conclusion by a critical essay on the invention of the forceps. Dr. Peter Chamberlen, who died in 1683, purchased the estate of Woodham Mortimer Hall, near Maldon, in Essex, some time prior to 1638. This residence remained in the possession of the family until 1715; and here, secreted in one of two closets opened into by a trap-door, a lady discovered four patterns of the midwifery forceps in 1815. Along with the forceps, three forms of the lever, three of the crotchet, and three also of the fillet were at the same time found. "The important discovery of these instruments in the house of Dr. Peter Chamberlen makes it unnecessary to consider the claims of the last two generations of the Chamberlen family as inventors of obstetric instruments." Dr. Aveling then shows reasons why the credit, though generally given, is most probably not due to Dr. Peter Chamberlen, the last of the name. In the first place he relies on the curious fact that there were *three* specimens of each class of instrument among those discovered at Woodham Hall, excluding a fourth forceps "of such rude construction as to be practically useless." And he reasons with obvious justice—"the rational and inevitable explanation, therefore, of this remarkable coincidence must be that the instruments found were those not only of Dr. Peter Chamberlen, but of his father and uncle, for the secret could scarcely have been kept if at the death of the two latter their instruments had been allowed to fall into any other hands than those of Dr. Peter Chamberlen." The soundness of this opinion is further supported by what we know of Dr. Peter Chamberlen's own professional life, that he was "in early possession of a secret which gave him a superior position as an obstetrician." Hugh Chamberlen, sen. in a preface to his translation of Mauriceau's Midwifery, says: "My father, brothers, and myself have *attained* to and long practised, a way to deliver women"—not *invented* and long practised" as Dr. Aveling observes. Moreover, Dr. Peter Chamberlen himself, in his "Voice in Rhama," says, "Fame begot me envie and secret enemies, which mightily increased when my father added to me the knowledge of deliveries."

"There is also undeniable evidence in the 'Annals of the Royal College of Physicians of London' that Dr. Peter Chamberlen's father and uncle possessed exclusive and superior skill in the treatment of difficult labours."

The honour, therefore, of having invented this instrument would seem to lie between Dr. Peter Chamberlen I. and Dr. Peter Chamberlen II., both sons of the original French refugee. Dr. Aveling accords the honour to the older brother on the strength of a statement by Smellie in the introduction to his Midwifery. Speaking of the forceps as used by the

Chamberlens, Smellie says : " And said to have been contrived by the uncle ;" which " uncle " can only apply to Dr. Peter Chamberlen I. We think that Dr. Aveling has made good his contention on the grounds of probability at least, and that by his painstaking industry he has done much to clear up one of the most interesting questions in the history of British midwifery.

We feel bound to add that the work is published exceptionally well, though here and there its pages are marred by misprints.

Medico-Parliamentary.

HOUSE OF LORDS.—Friday, July 20th.

ARMY HOSPITAL SERVICE.

Viscount Bury rose to call attention to the report of the Committee on Army Hospital Services, and to move—"That while the individual medical officers in Egypt behaved admirably well, the system under which they worked did not successfully stand the strain put upon it ; that the military authority exercised by medical officers is inconvenient, and that discipline in hospitals ought to be administered by combatant officers, leaving to the medical officers medical duties only ; also that medical officers ought to be attached to regiments instead of being detailed for duty day by day from station and other hospitals."

The Earl of Morley concurred with the noble Lord in the tribute which he had paid to the energy and ability of the medical officers, and to the devotion of the lady nurses in the Egyptian campaign. He admitted that there were some defects in the administration of the hospital service, but he would remind their Lordships that the campaign was an exceedingly rapid one. The medical results of the campaign were somewhat remarkable. Taking the period from the 17th July to the 10th of October, which embraced the time from the first landing of the troops to the conclusion of active operations, there were 378 wounded non-commissioned officers and men admitted to hospital, of whom only eleven died, and admitted from other causes there were 7,212, of whom 79 died. There was a total absence of pyæmia, and not a single case of loss of sight.

The Duke of Richmond and Gordon considered that of the many changes introduced into the Army of late years the alteration in the medical system was, perhaps, worse than any of them. The question of economy should not stand before the health of the Army, and he hoped the system would be changed, or modified, instead of, as suggested, being extended to the Household troops, hitherto excepted.

The Duke of Cambridge had the strongest belief in the excellence of the medical officers of the army. If anything had gone astray in their department it was the system, and not the individuals who were at fault. He should very much like to see the present system modified, so that medical officers, for at least two or three years, should be attached mainly to a regiment. It was essential to the health of a regiment, and for the general efficiency of the medical department, that this should be the case. He regretted to some extent the charges which had been made, but he had no desire to revert, only to modify, the existing system to the extent he had mentioned. He hoped it was possible that the discussion which had taken place as well as the general feeling in the army, which entirely accorded with the views he had expressed, would bring about this modification. He believed the change would be very beneficial to the army, and that it would not be found out of accord with the prevailing system, which, with the limitation he had suggested, would continue much in its present form.

After a few further remarks, Viscount Bury expressed himself satisfied with the discussion that had taken place, and the motion was by leave withdrawn.

◆

Mr. W. Stokes, Professor of Surgery in the Royal College of Surgeons in Ireland, has been nominated by the President of the Royal College of Surgeons of England to a seat on the Council of the Association for Advancement of Medicine by Research.

PREVENTION OF CHOLERA.

On Monday afternoon last a meeting of the National Health Society was held at the Parkes Museum, under the presidency of Sir Joseph Fayrer, K.C.S.I., to consider what measures of prevention should be taken in the event of cholera spreading to this country. Mr. Ernest Hart read a paper on the subject, in which he detailed the history of previous epidemics, and sketched the manner in which precautions should be adopted, with especial reference to pure drinking water and efficient ventilation. Sir Joseph Fayrer, in his opening address, dwelt on the necessity for considering the question in reference to any possible extension of the disease to this country. Happily, so far as he knew, there was no indication of it at present, but previous experience taught that such extensions did take place. The Government and the sanitary authorities had been, he said, alive to the importance of the matter which had been carefully studied, and much information of a practical character had been obtained. It was true there might be, and, in fact, there was some difference as to the nature and causation of the disease ; but so much was known as to the laws that regulated its propagation and its diffusion, that we may be prepared, in the event of cholera coming to this country, to treat it as of comparatively little importance, or, at all events, to await its arrival with something of indifference. He thought it was very satisfactory to see the calm and dignified way in which the English nation had treated the matter. It was a pleasant contrast to the excited view which was taken by other Powers in reference to quarantine and coercive measures—measures which it had been satisfactorily shown did no good, but, if anything, intensified the mischief, and rather tended to increase than diminish the disease.

◆

DR. BANKS.

We learn that Her Majesty has been graciously pleased to propose to confer the honour of knighthood on our esteemed colleague Dr. Banks, and that he has most respectfully, and at the same time gratefully, begged to be allowed to decline the honour. It is always a difficult thing to decline any mark of favour at the hands of the Sovereign, but in this instance we believe Dr. Banks could not have done otherwise.

So long as higher titles are conferred on members of our profession elsewhere, his acceptance of a lower dignity by one selected by the Irish profession for the highest honours they had it in their power to bestow would be an acknowledgment that they occupied a lower rank than their fellows in other parts of the kingdom, an admission Dr. Banks could not and would not consent to make. On the creation of the Irish Academy of Medicine, Dr. Banks was unanimously selected as President—a selection that has contributed very largely to the success the Academy has attained. The University of Dublin put him in their foremost place by making him Regius Professor of Physic. A leading member of the Senate of the Queen's University and of that of its successor, the Royal University, they both selected him as the most worthy to represent them on the General Medical Council. He is, moreover, Senior Physician in Ordinary in Ireland to Her Majesty herself ; and under the circumstances, however gratifying it might be to Dr. Banks himself, as an individual, to receive any mark of favour from his Queen, we hold that his duty to his profession and to the positions they have given him rightly precluded him from accepting the proposed honour.

THE PROFESSION IN IRELAND.

THE Lord-Lieutenant has sent the following letter to Dr. Moore, in reply to the memorial referred to in our last issue :—

"Dublin Castle, July 21, 1883.

"Sir,—I am desired by the Lord-Lieutenant to acknowledge the receipt of the memorial from certain members of the medical profession in Ireland, which was placed by you in Mr. Hamilton's hands on July 17.

His Excellency is unable to consider that the bestowal of honours by the Crown can be made the subject of discussion between him and any public body, and therefore, while entertaining great respect for those who addressed him, he must decline to discuss with them the question which they have brought under his notice. His Excellency, however, wishes to assure them that Mr. Gladstone is fully aware of the high estimation in which the medical profession in Ireland is held, and desires to do justice to its members, and I am to add that the Lord-Lieutenant heartily shares in these feelings.—I am, sir your obedient servant, ALFRED E. TURNER, MAJOR, Assistant Private Secretary.

◆

Pass Lists.

University of Dublin.—The following candidates, having undergone the necessary examinations, received their respective degrees on June 29th :—

Bachelor in Surgery.

Beveridge, Edmund Francis.
Braddell, Monckton O'Dell.
Cowen, George.
Digty, Cecil Arthur.
Drury, Francis James.
Dwyer, Frederick Conway.
Fagan, Charles Joseph.
Hamilton, Charles Wolfe.
Haughton, Thos. Wilfrid.
Oldham, Hugh Falconer.
Poland, Chas Thos.
Scott, John Harrison.
Thompson, Henry Neville.
Wright, A. Edward.

Bachelor in Medicine.

Beveridge, Edmund Francis.
Blandford, H. Edmund.
Blood, Chas. Holcroft.
Braddell, Monckton O'Dell.
Cochran, John James.
Cowen, George.
Digby, Cecil Arthur.
Dobson, Geo. Magill.
Drury, Francis James.
Dwyer, Frederick Conway.
Fagan, Charles Joseph.
Fenton, William G.
Haughton, Thomas Wilfred.
M'Quaide, Henry.
Oldham, Hugh Falconer.
Poland, Charles Thomas.
Scott, John Harrison.
Sproule, Robt. Edw.
Thompson, Henry Neville.
Wright, A. Edward.
Driver, Frederick John (Cantab. *ad eundem gradum*).

Master in Surgery.

Bourke, Isidore M'William.
Cosgrave, Ephraim MacDowell (*stip. cond.*).
Gloster, James.

Licentiate in Medicine.—Sullivan, Green James.

Doctor in Medicine.

Bourke, Isidore M'William.
Denning, Robert Nirkle.
Driver, Frederick John.
Fawcett, Edward.
Kirkpatrick, John R.
Mason, Samuel R.
Smith, Travers Robert Montgomery.
Ward, Montgomery A.
Windle, Bertram Coghill.

King and Queen's College of Physicians.—At the July examinations the following candidates obtained the licences in Medicine and Midwifery of the College :—

Midwifery.

Andrew, Letitia Harvey
Byrne, Hugh John
Cleary, Michael Richard
Cradock, Lucy Elizabeth
Ensor, Edwin Thomas
Fitzgerald, Arthur Ormsby
Heuston, Frederick Samuel
Keenan, James
Kenealy, Arabella Madonna
Kenny, William
Lalor, Joseph
Long, Mark Henry
M'Ginity, Bernard A.
Neill, John
Roughan, Geo. Francis
Sheperd, Albert Wilberforce
Taylor, Rogers Wetherell Gore

Medicine.

Andrew, Letitia Harvey
Blake, Anthony Lawrence
Byrne, Hugh John
Clayton, William Mayne
Cleary, Michael Richard
Cradock, Lucy Elizabeth
Drought, Percy James
Ensor, Edwin Thomas
Fitzgerald, Arthur Ormsby
Fitzpatrick, James Vincent
Forde, Maurice
Hamilton James
Heuston, F. S.
Keenan, James
Kenealy, Arabella Madonna
Kenny, William
Lalor, Joseph
Lane, James
Long, Mark Henry
M'Craith, John R.
M'Gee, William
M'Ginity, Bernard A.
Maher, Charles Henry
Martin, John
Moorhead, Henry
Neill, John
Nolan, John Robert
O'Reilly, Peter Joseph
Roughan, George Francis
Russell, Bartholomew Taylor
Sheperd, Albert Wilberforce
Torney, George Parsons

The following Licentiates have been admitted Members :—

Beamish, Thomas
Clarke, Anne Elisabeth
Gore, Albert A., Surgeon-Major A.M.D.
Lynch, Gilbert
Roberts, Bransby
St. George, Geo. Lombe
Stephenson, Ed. A.
Stoker, W.

Royal College of Physicians of Edinburgh.—The following candidates have passed the final examination for the licence of this College :—

Alexander, Frederick William.
Aspinall, Samuel.
Baxter, William Whittington.
Cotton, James Milton.
Dodson, Arthur Edward.
Duncombe, Chas. Edwd. Berkeley.
Duncombe, Truman Wallace.
Gordon, Arthur Henry.
Gracie, Charles Batten.
Griffiths, John.
Hewish, Edgar Milne.
Hynes, Edward Charles.
Kinver, John Percy Holyoake.
Levi, Rueben.
Mayo, Frank Herbert.
M'Cullough, James Henry.
M'Naughton, John Alexander.
Parsloe, Henry Heath.
Phillpot, George Frederick.
Rhodes, Thomas.
Rix, Wm. Knibb.
Smailes, Robert.

Royal College of Surgeons of England.—At the meeting of the Council held on the 12th inst. the following Member was admitted a Fellow of the College :—

Smyth, John E., B.A., L.R.C.P.Ed., of Clapham.

The Membership.

The following candidates having passed the required examination for the diploma, were admitted Members of the College on Monday, July 16th :—

Barefoot, John R., L.R.C.P.Lond.
Beck, Geoffrey S., M.B.Toronto.
Bird, Frederic Dougan, M.B.
Cameron, Chas. E., M.B.M'Gill.
Ford, Geo. W., L.R.C.P.Ed.
Fraser, Thomas Alex., M.B.Ed.
Gandevia, N. R., L.R.C.P.Lond.
Gardner, Thomas F., L.S.A.
Hunter, William, M.B.Ed.
Jones, J. E. Evans, L.R.C.P.Lond.
Khan, Mohamed I., L.R.C.P.Lond.
Macdonald, W. H., M.B.Toronto.
M'Kenzie, Archibald, M.B.Ed.
Mackinnon, Frank L., M.B.Ed.
Nattress, William, M.B.Toronto.
Nicolet, Gustavus P., M.B.Ed.
Priestley, Joseph, M.B.Ed.
Reckitt, J. D. T., L.R.C.P.Ed.
Rodman, George H., M.B.Dub.
Rudge, Henry T., L.R.C.P.Ed.
Shuter, Charles Y., L.S.A.
Vincent, G., M.B.Aber.
Ward, Allan Ogier, M.B.Ed.
Willett, Edgar William, L.S.A.
Woodbury, John M'Gaw, M.D.

The following were admitted Members on Tuesday, July 17th:

Baxter, W. W., L.R.C.P.Ed.
Beebe, Charles Edward, L.S.A.
Cox, John Henry, L.S.A.
Craig, James, M.B.Ed.
Donald, Archibald, M.B.Ed.
Ellis, John Lloyd, L.R.C.P.
Holyoake, John P., L.R.C.P.Ed.
Jones, John Hervey, L.S.A.
Lawry, Thos. Spencer, M.B.Ed.
Lloyd, Henry Sanderson, M.B.Ed.
Mackay, George, M.B.Ed.
Nieuwoudt, Gerrit, M.B.Ed.
Parsloe, Henry H., L.R.C.P.Ed.
Paterson, Andrew M., M.B.Ed.
Phillpot, Geo. F., L.R.C.P.Ed.
Stillito, William Alsope, L.S.A.
Sutcliffe, Victor E., L.R.C.P.Ed.
Welchman, Eliot W., L.R.C.P.Ed.
Wilson, Theodore S., M.B.Ed.

The following were admitted on Wednesday, July 18th :—

Dunn, John E., L.R.C.P.Ed.
Foster, Albert Ernest.
Gordon, Arthur H., L.R.C.P.Ed.
Gostling, William Ayton.
Jackson, Arthur Molyneux.
Kitching, J. L. Walton, L.S.A.
Morgan, Llewellyn A., M.B.Durh.
Overton, Arthur Horncastle.
Papillon, James William, L.S.A.
Pedley, Richard Denison.
Roberts, Arthur H., L.R.C.P.Lond.
Southcombe, Arthur George.
Stericker, George Frederick.
Travis, William Owen.

The following candidates passed on Thursday, the 19th inst.:

Callender, Gerald.
Cardozo, S. N., L.R.C.P.Lond.
Childe, Charles P.
Ellis, Charles C.
Griggs, William A.
Hillaby, Arthur.
Parry-Jones, Maurice, L.S.A.
Linnell, Alfred.
Llewellyn, D. W. H., L.R.C.P.Lond.
Maughan, James, L.R.C.P.Lond.
Phillips, F. B. W.
Sanson, Charles L.
Tresidder, H. I., L.R.C.P.Edin.
Wigg, Henry H.

The following candidates passed on Friday, the 20th inst. :—

Beaumont, Edgar.
Brown, A. T. F., L.S.A.
Clark, Arthur W.
Cuolahan, John H.
Floyer, William W.
Green, C. D., L.R.C.P.Lond.
Hunter, George D.
Kendall, George.
Lilburne, James T., L.S.A.
Powell, Herbert E.
Powell, John J.
Robinson, C. S., L.R.C.P.Lond.
Robinson, Henry B.
Sharpley, Edward.
Williams, Robert R.
Wilson, Edward.
Woodson, Adolphus A.
Wright, G. R. M., L.R.C.P.Lond.

Notices to Correspondents.

SUPERANNUATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I am now nearly forty years a dispensary medical officer, and anxious to get out of harness. I shall feel greatly obliged if you will say, can I apply for superannuation conditionally, that is, can I go before the Board of Guardians and say that I am anxious to retire, provided they grant me superannuation; and if they will not agree to do so, that I will retain my position. I believe that were I to apply I would get considerable support from the *ex-officios* and from many of the elected guardians.

Yours, &c.,
July 18, 1883. A CANDIDATE FOR SUPERANNUATION.

[Yes. If you send to the guardians a letter stating your desire to retire if pensioned, and if you get a guardian to give notice thereupon of a motion that it is desirable to grant you a defined pension on your retirement, the motion will be quite legal and in order for discussion, and you need not resign until it has been passed, and if it does not pass you may hold your office. If it does pass, a further resolution, fixing the amount of pension, must be proposed, and you must resign before it comes on for discussion; but five minutes beforehand will be sufficient. This is the law, whatever the custom may be.—ED.]

Mr. Makuna (Melksham).—The subject is under consideration.

Volunteer Medical Organisation.—In furtherance of this movement, to which a leader was devoted in our last, we are requested to announce that a meeting of volunteer medical officers will be held at Liverpool, in one of the section rooms, on Wednesday, August 1st, during the meeting of the British Medical Association, when an address by Surgeon-Major Evatt, A.M.D, will be delivered, and several resolutions will be proposed.

FOREIGN DEGREES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I see a letter in your last issue from "Inquirer" asking me several questions. Will you allow me to state that I must decline to be catechised by anonymous writers.

Yours truly,
H. J. HARDWICKE.

Dr. Hy. Kennedy on "Some Forms of Dilatation of the Colon" shall appear in an early number.

Dr. Bell Taylor (Nottingham)—We hope to find space for your communication in our next.

An Intending Candidate.—The date was supplied to us by the agent of H.M. Government. Having drawn his attention to your letter, he has authorised the necessary correction. Thanks.

IRISH COUNTY INFIRMARIES.

A correspondent asks: 1. Can a case of accident be refused admission at a County Infirmary, no matter to what county the patient belongs? 2. Is a recommendation from a Governor for such admission necessary? 3. Is there any recent instance where the presentment for the support of a county infirmary has been successfully opposed at Presentment Sessions, sanctioned by the Grand Jury, and on appeal confirmed by the superior courts?

[1. There is nothing in the Infirmary laws to prevent a patient from another county being received, but the ratepayers might object. 2. A Governor's recommendation is usually dispensed with in urgent cases, and is not necessary according to law. 3. There is no such case, but in the recent case of the Kildare Infirmary, the presentment was sanctioned by the Grand Jury and refused by the ratepayers, and the Judge ordered payment of the salary of the surgeon, but nothing else.—ED.]

Esprit de Corps.—Your reply is unfortunately crowded out of present number; space will be reserved in our next.

THE RECENT PASS LIST FOR THE K.Q.C.P.I.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I observe in the *Medical Press and Circular* for July 18 a statement that Miss Arabella Kenealy obtained first place out of fifty candidates at the recent examination for the Licence in Medicine of this College This statement is not quite accurate, as the names of the successful candidates are not arranged in order of merit, but alphabetically, and the number of candidates at the recent examination was not fifty—but forty.

Kindly insert this correction in your next publication, and oblige

Yours faithfully,
JOHN WILLIAM MOORE, M D. Dub.,
Fellow and Registrar.
July 20, 1883.

Mr. Jamieson.—"Studies in Microscopical Science," issued weekly by Messrs. Baillière, Tindall, and Cox, and with each number of which a prepared slide is given, cut and mounted by Mr. Cole, is the most likely source from which to gain what you want.

A. K. G. asks if a mortality of forty per cent. in hospital practice is a large one. Most persons will probably agree with us that it is, and that any institution exhibiting such an unusual death-rate was seriously defective in some important respect. We shall be glad to have further particulars from our correspondent if his query has reference to any actual hospital.

Dr. Drew.—Oophorectomy is not regarded with a high degree of favour in this country, and no one would think of resorting to it under the conditions you suggest, nor indeed save as a final and desperate remedial attempt.

Dr. Hanson.—It would be out of place for us to discuss the comparative merits of degress conferred by different Universities, nor could it result in gain one way or another.

Auricula.—Professor Humphry's work on the skeleton is most adapted to give you the information you require. Owen's Anatomy of the Vertebrata also will afford useful details likely to be of assistance in the study you are making.

A much-needed Bill.—The Cincinnati City Council has introduced a Bill for the wholesale punishment of quacks, and which would seem to be eminently necessary, since the following is a sample of the advertisements published by the unlicensed doctors: "*All* obstructions to menstruation, from *any* cause, removed."

R. L. K.—More extended experience will prove to you that a very considerable proportion of older therapeutic measures are inconsistent with modern progress, and you will constantly regret having confined your attention to what will practically have to be unlearned again. Ringer's Therapeutics is the standard work, and must certainly be consulted. Naphey's volumes on Medical and Surgical Therapeutics will be of great service also.

Arsenicus.—Pemphigus is characterised by the presence of bullæ, most frequently on the arms, but not confined to any particular region. Arsenic is beyond all other drugs the remedy which has the most decided influence on the disease. Fowler's solution is as good a form as any that can be adopted.

C. C. (Liverpool).—The operation is not often performed, unless there is some pressing reason why it should be resorted to. The presence of varicose veins does not necessitate any condition of danger, and mere inconvenience cannot be held a sufficient reason for running the risk incurred by such an operation as that for the radical cure of varicocele.

Vacancies.

Birmingham Children's Hospital.—Assistant Resident Medical Officer Salary, £40, with board. Applications to the Secretary by the 30th inst.

Brompton Consumption Hospital.—Resident Clinical Assistant. Applications to the Secretary before August 4th. (See Advt).

Clifden Union, Clifden.—Dispensary Medical Officer. Salary, £90, and £10 as Sanitary Officer. Election, August 4th.

Downpatrick Lunatic Asylum.—Assistant Resident Medical Officer. Salary, £100, with apartments, rations, &c. Election, August 4th. (See Advt.)

Downpatrick Union—Dispensary Medical Officer and Sanitary Officer. Combined Salaries, £115. Applications by the 28th inst. (See Advt)

Enniscorthy District Lunatic Asylum.—Medical Superintendent. Particulars as to duties and emoluments obtainable at Dublin Castle. (See Advt.)

Leeds School of Medicine.—Curator. Salary, £80 per annum, with furnished apartments, &c. Applications to Dr. Churton, Park Sq., Leeds.

Middlesex County Asylum.—Assistant Medical Officer to the Male Department, Colney Hatch. Salary commencing at £150, with board. Printed forms of application will be supplied on request.

Royal Free Hospital, London.—Junior Resident Medical Officer. Applications to the Secretary. Board and residence. No salary. (See Advt.)

Salop Infirmary, Shrewsbury.—House Surgeon. Salary, £100, with board and residence. Immediate application to the Board.

Strabane Union, Strabane.—Dispensary Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, August 15.

Strokestown Union, Strokestown Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, July 27.

Appointments.

Baker, G. I., L.K.Q.C.P.I., Resident Obstetric Assistant to Westminster Hospital.

Butler, G. E., M.R.C.S., Junior House Physician to Westminster Hospital.

Clapp, R., L.R.C.P. Lond., M.R.C.S., Assistant Medical Officer to the Devon County Lunatic Asylum.

Fergus, S., M.D.Q.U.I., M.Ch., Medical Officer to the Blackwater Town Dispensary, Armagh Union.

Births.

Graham.—July 15, at Sandymount, the wife of Wm. Graham, Fleet Surgeon H.M.S *Achilles*, of a son.

Hartland, July 14, at the Friary, Villiers Town, co. Waterford, the wife of John F. Hartland, M.D.R.U.I., of a son.

Kiernander.—July 19, at St. Charles Square, Kensington, the wife of Surgeon-Major Wm. C. Kiernander, A.M.D., of a son.

Lees, July 18, at 2 Thurloe Houses, South Kensington, the wife of D. B. Lees, M.D., F.R.C.P., of a son.

Macan.—July 16, the wife of Arthur V. Macan, M.B., F.K.Q.C.P., Master of the Rotunda Hospital, of a daughter.

Moore.—July 22, at 40 Fitzwilliam Square, West, Dublin, the wife of John William Moore, M.D., F.K Q.C.P., of a son.

O'Kelly.—June 9, at Maynooth, the wife of Thomas E. Talbot O'Kelly, L.R.C.S.I., of a son.

Marriages.

Edgar—Clayton.—July 21, at the Church of the Holy Ascension, Settle, Yorks, James W. Edgar, M.D., of Settle, to Susanna, eldest daughter of the late Rev. Wm. Clayton, rector of Bentham.

Edwards—Wilcocks.—July 17, at St. James's, Notting Hill, W., Thos. R. C. Edwards, M.R.C.S. Eng., L.R.C.P. Ed., &c., son of Dr. Edwards, of Gloucester Crescent, Hyde Park, to Laura Elizabeth, third daughter of the late J. C. Wilcocks, of Exeter, Devon.

Hay—Batters.—July 18, at St. Andrew's Church, Stanstead Abbotts, Herts, John Home Hay, M.D. Edin., M.R.C.S. Eng., of Alloa, N.B., to Margretta, third daughter of John Batters, Esq, of Stanstead Abbotts.

Deaths.

Croker.—July 12, suddenly, at Malvern Link, Worcestershire, John Rees Croker, M.R.C.S., &c., aged 62.

French.—July 16, at Bath, suddenly, Anna Sophia, the wife of James French, M.R.C.P., formerly of Neath.

Houston.—July 16, at Kirkcaldy, Patrick Cruikshank Houston, M.D.

Mease.—July 19, at the Infirmary House, Cavan, after a few hours' illness, Andrew Mease, M.D., aged 71.

Stewart.—July 17, at Grosvenor Street, Alexander Patrick Stewart, M.D., aged 70.

Thurston.—July 10, at Sandown, Isle of Wight, George James Thurston, M.R.C.S., L.R.C.P. Ed., aged 56.

Williams.—July 14, at his residence, The Hollies, Southport, William Jay Williams, M.D., late of Manchester.

NOTES ON CHOLERA AND ITS TREATMENT.

By Surgeon-General C. A. GORDON, M.D., C.B.,
Honorary Physician to Her Majesty the Queen.

DIARRHŒA may occur as an independent affection in times of cholera, or it may happen as an early stage of the latter disease. When cholera prevails it is difficult to decide correctly and with precision where diarrhœa as such ends, and where distinctive cholera begins. The symptoms of the two affections differ in degree rather than in kind; but it is usually considered that the retention of colour in and slower progress of diarrhœa by itself are to be taken as indicative of the milder malady.

Diarrhœa, when it occurs as a premonitory stage of cholera, has a duration seldom exceeding three days. As regards the prevalence of this affection among masses of population, it has been observed to vary from a few days to several weeks. In 1866 statistics regarding this point were taken in London. In 41 examples on that occasion recorded the duration of the diarrhœa in 3 cases was 12 hours, in 1 case 18 hours, in 1 case 19 hours, in 7 cases 33 hours, in 12 cases 2 days, in 6 cases 3 days, in 2 cases 4 days, in 2 cases 5 days, in 1 case 6 days, in 1 case 7 days, in 2 cases 2 weeks, in 1 case 5 weeks, in 1 case 8 weeks. The general result of these observations shows that in more than half the number of cases diarrhœa preceded the more marked symptoms by less than three days. On that occasion in London there was a subsidence of diarrhœa before the outbreak of cholera. A similar subsidence had preceded the outbreak of 1848-9 and 1853-4.

In some instances epidemics of diarrhœa have been considered to be really epidemics of cholera, although occurring in that form. In 1836 this was the case in the Indo-Chinese fleet. On that occasion the epidemic of diarrhœa which prevailed was considered to take the place of cholera which had in previous years occurred in the same fleet. At Huddersfield in 1849 diarrhœa and cholera prevailed simultaneously in so defined a manner that the cause which produced them both was considered to be identical, only the form of resulting disease to differ in different individuals. At Oxford in 1852 deaths took place by diarrhœa without the cases passing into confirmed cholera. And similar occurrences are noticed in other epidemics of the disease.

Persons coming from infected localities have been attacked with diarrhœa within a period extending to fourteen days from the date of their departure, the disease in them undergoing no farther development; and yet confirmed cholera occurred in the locality into which such persons had entered. Occurrences of this nature happened in France during the epidemic of 1855—notably at St. Germain, Melissy, St. Barthèlemy, and Villedieu. The Constantinople Commission acknowledged that cholera could be propagated in this manner.

It has come to be acknowledged as an axiom that the more severe the impending epidemic of cholera the shorter is the period of premonitory diarrhœa. In young persons diarrhœa in connection with cholera is considered to be of more frequent occurrence than it is in those more advanced in years. In a number of instances cholera has manifested a partiality to individuals habitually subject to diarrhœa.

Diarrhœa is said to occur more frequently in attendants on cholera patients, and in them to take the place of the more developed disease. In 1873 this circumstance was noticed in connection with the epidemic at Ottawa.

But although diarrhœa often precedes cholera, this does not happen invariably. There was no premonitory diarrhœa on the occasion of the cholera outbreak in the 86th Regiment at Kurrachee in 1846; none in the Madras epidemic of 1848. In the French epidemic of 1855 diarrhœa is mentioned by 97 reporters; by 15 its occurrence is considered exceptional. In the Crimea in that year our troops were seized, in many instances, with collapse of cholera without any premonitory symptoms whatever. At Gateshead in the same year 55 persons who went to bed in perfect health on the 25th of December were attacked with cholera before sunrise on the 26th; and of the number so attacked, 32 were dead before sunset. In 1861 there was no marked prevalence of diarrhœa before or during the epidemic of cholera at Delhi. In 1866 diarrhœa, and indeed all other premonitory symptoms, were absent on the occasion of the cholera outbreak at Mean Meer. At Peshawur the attack of cholera in the 42nd Highlanders was sudden, and unpreceded by premonitory symptoms. Other instances could be given in illustration of the fact that, although on occasions cholera is preceded by diarrhœa, this is by no means an invariable occurrence.

The success of treatment applied in cases of cholera depends in a very great degree upon the early use of that treatment. For example, in London in 1849 there were treated 43,737 cases of "premonitory" diarrhœa, and of this number 58 only developed into cholera. In that year throughout England there were treated 130,000 cases of diarrhœa, of which number only 250 passed into cholera. A question was raised as to whether many of the cases so treated were not cases of simple diarrhœa. Perhaps they were; it is impossible to say. From calculations made in Glasgow in reference to the epidemic of that year, it has been stated that of persons treated within the first six hours after attack by cholera 21 per cent. died; of those first treated between six and twelve hours after attack, 33 per cent.; of those between the twelfth and twenty-fourth, 45 per cent.; and of those treated later, 66 per cent. In India the importance of early treatment is universally recognised, and special orders on this point are enforced in respect to soldiers. In 1877 the observance of such orders was followed by important success at Madras.

Briefly, the remedies administered in the stage of premonitory diarrhœa comprise carminatives, antispasmodics and astringents.

In the treatment of fully-developed cholera remedies of the most diverse nature have been used from time to time. Perhaps the earliest method on record was that which of late years has been called the "eliminative." That method dates from the year 360.

In the sixteenth century venesection, ligatures to the head, limbs and loins, acupuncture, pepper in rice-water as a drink and applied externally, were the means employed. After the violence of the disease had passed, purgatives were given.

In the seventeenth century the natives of India withheld liquids from patients affected with cholera, and cauterised the soles of their feet. Among the remedies administered were diffusible stimuli, saffron, opium, vegetable astringents, and ammonia. Towards the end of that century, and in the early part of the eighteenth, the French Missionaires at Trichinopoly administered to the cholera patients "un peu d'eau bénite et se mit à réciter quelques prières," with the happy result, as stated by themselves, that "le malade guérit subitement."

Among the remedies used in the eighteenth century were the following:—Calumba root in 1756; cassia fistula and rhubarb in 1761-63; opium and rice-water in 1769; Glauber salts with tartrate of antimony, in doses of one-eighth of a grain, in 1782; Madeira wine, laudanum and cordials also in that year; castor oil at Arcot in 1787; large doses of opium at Batavia in 1789.

During the portion of the nineteenth century already gone, methods of treatment in their nature absolutely the opposite of each other have been used. In 1817 large doses of calomel, combined with small quantities of opium, were given. In 1831 emetics of ipecacuanha were said to have "acted like a charm;" on the same occasion sulphur and phosphoric acid internally were given. In 1832 venesection, used, as already stated, in the sixteenth century, was reverted to; in 1849 the same method was for the third time practised. Naphtha was employed for the disease as it occurred among the Prussian troops in the Caucasus; and, under the name of "elixir of Woreneje," that substance is believed to have been employed for the same purpose in Russia. In 1848-9 naphthaline and petroleum were given internally in the United Kingdom.

The use of opium vaunted by some writers is utterly condemned by others. During the epidemic in France, 1855, opium was extensively used; the result assigned to such use being that in some instances living persons were buried while in a state of narcotism only. There are many medical officers of great experience who assert that it is chiefly or only among patients thus treated that the severe train of symptoms known as "secondary fever" occur.

With regard to ipecacuanha, about twenty reporters record their experience with that drug. Of 4,180 patients treated by means of large doses of it, 2,509 died.

Evacuants, praised by some writers, are by others stated to be deadly. The same remark applies to the use of tobacco fumes.

Antispasmodics—notably, ether and chloroform—are used with the greatest advantage against spasmodic phenomena in the course of the disease.

Among the means applied externally and variously reputed have been frictions and excitants; hot baths, with and without aromatic herbs; bags of hot sand to the hands and feet; the application of cold; galvanism, &c., &c.

Among various other remedies used from time to time are the following, they being but a very few out of a long catalogue, namely:—Hot negus, with grated nutmeg; quinine, strychnine, and nux vomica; sulphate of copper; homœopathy, practised, it is said, during the epidemic in France with sad results; hypodermic injections of various kinds; inhalation of gases; transfusion of blood and of different saline mixtures; purges; astringents; carminatives; alkalies; sulphur; sulphuric acid; chloral, both by the mouth and hypodermically; acetate of lead; tartrate of antimony; stimulants; preparations of iron; hydrosulphuret of ammonia; olive oil; yeast; eupatorium, &c. For a time *Sumbul*, the product of Euryngium Sumbul, N. O., Umbelliferæ, was used. In 1864 a solution of permanganate of potass was given in India.

In order to account for the insuccess of medical treatment in cases of declared cholera, the circumstance must be borne in mind that for the time being the function of absorption is in abeyance; especially is this the case in the algid stage of the disease.

But, while on the one hand there is no certainty of saving the life of a person attacked with cholera, neither is it right or justifiable to despair as to the results of means reasonably employed, even in cases the most desperate.

ON SOME IMPLICATIONS OF DISSOLUTION OF THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.C.P., F.R.S.,
Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed.

(*Continued from page 66.*)

I shall state the scheme briefly, *and only as regards the motor centres*, assuming for simplicity, which I do not believe, the middle and highest centres to be purely motor. This artificial simplification must not be forgotten. Another simplification is that, for the most part, we speak of the cerebral system only; we almost ignore the divisions of the cerebellar system, especially the higher divisions. Still another simplification, to be remedied later when we consider Broadbent's hypothesis, is that we speak of centres of one half of the nervous system only. As the terms lowest, middle, and highest centres are used as proper names, as well as to indicate different evolutionary levels, there is no impropriety in such an expression as "two lowest" centres, nor in saying that the highest motor centres are in front of the middle. The order of cerebral centres is as follows:—

Lowest Centres.—A lowest centre is one which represents some limited part of the body most nearly directly; it is a centre of simplest, and yet it is one of compound, co-ordination (in some cases plexuses of nerve trunks show this clearly). Not only are the spinal anterior horns lowest centres, but so also are the higher homologous nuclei. Thus the nuclei representing most nearly directly the ocular muscles, the nuclei representing most nearly directly parts concerned during circulation, are some lowest centres, as certainly as the lumbar nuclei are some others. The sum of these representations in detail is the first, most nearly direct representation of the whole body.

Middle Centres.—A middle centre represents over again in still more complex, &c., combinations what many or all of the lowest have represented in comparatively simple combinations; thus, it represents a less limited part of the body. The middle centres are re-representative; they represent parts of the body doubly indirectly; they are centres of doubly compound co-ordination. They are supposed to be made up of the parts in the so-called psycho-motor region, and also of the ganglia of the corpus striatum. The sum of these representations of wider districts is the second, and is a doubly indirect representation of the whole organism. (*a*)

Highest Centres.—The highest centres (we are speaking of motor centres only) are supposed to be parts in front of the middle. They represent over again in more complex, &c., combinations, the parts which all the middle centres have re-represented, and thus they represent the whole organism; they are re-re-representative; they represent parts of the body triply indirectly. They are centres of triply compound co-ordination. The sum of their representations is the third and a triply indirect representation of the whole of the body. This statement implying that the highest motor centres of each half of the nervous system represent both sides of the body is an anticipation of what will be said when considering Broadbent's hypothesis.

Putting the main part of the foregoing scheme most generally, we say that there are many lowest, many middle, and many highest centres. From increasing evolution of centres there is, in each of the centres making up the higher level, increase in complexity of representation of parts of the greater range represented and increase in speciality of representation. Thus the highest centres, the climax of representation, represent impressions and movements of all parts of the organism (range), each unit represents the whole organism (complexity), each unit represents the whole organism differently from all other units (speciality). Taking note of the highest sensory centres also (we have neglected the hierarchy of sensory centres), the highest centres are the anatomical substrata of consciousness.

We have spoken of Evolution as if it were a "necessary" process, which it is not. We spoke as if the higher centres were so to speak evenly evolved out of their lower. No doubt there is in the highest centre what we may call Internal Evolution—re-combinations of nervous arrangements each of which has been organised during complete correspondence of the organism and its environment. If not there would be no trains of thought independent of present actual experiences, and none differing from past actual experiences; it is quite certain that there are, in dreams most strikingly. Any recombinations that are permanent imply new nervous arrangements. No doubt, therefore, peripheral parts serving, or rather as they serve, in visual and tactual exploration, will be proportionally represented very much more specially than such parts as the legs in the highest centres. Similarly for parts serving, or parts as they serve, during emotional states. For the present these considerations can be ignored; but for some purposes they must be taken into account, as when dealing with the special symptomatology of epileptic paroxysms.

Very briefly we speak of the dynamics of the nervous system. In what is called a voluntary action, as well as in many others not so called, all orders of centres are engaged. Manifestly a voluntary action is one of the whole organism, and is so in two ways. It begins, we speak of the motor part of the process only, with activity of some part of the centres representing the whole organism; it engages all orders of centres. A normal discharge starting in some elements of the highest centres overcomes the resistance of some of the middle, next the resistance of some of the lowest centres is overcome, and the muscles (*a*) are ultimately moved in a particular way (we still neglect the cerebellum). The process is from the least towards the most organised; as this is the order of increasing resistances, it results that from slight energising in the highest centres of nervous arrangements representing movements of the whole organism there may occur at the periphery movement of but a limited part, say of one finger. A fit of epilepsy is an excessive caricature of the normal physiological process during what is called a voluntary action.

The existence of plexuses betwixt the highest and middle, betwixt the middle and lowest, and betwixt the lowest and the periphery, is of necessity assumed in the foregoing. There are integrations betwixt different parts of centres of the same rank. These we must take note of in order to understand how discharges of collateral nervous arrangements occur from the primal discharge of a part highly unstable. It is not said the more perfectly integrated the higher the centre; no doubt the highest centres, being the least organised, are least perfectly integrated, although they have most lines of integration.

Now we return to cases of "discharging lesions" of the highest centres, and take note of the subordinate (middle and lowest) centres. It is unfortunately in so complex a subject impossible to consider things *seriatim*. We have been obliged to anticipate conclusions to be reached later by assuming that the highest centres of each half of the brain represent both sides of the body—the whole organism.

We suppose the discharge of part of the highest centres to be very excessive—a case of *le grand mal.* Upon discharge of a highly unstable part of the highest centres, which part we likened to a fulminate, there are secondary "downward" discharges of healthy middle and then tertiary discharges of healthy lowest centres, and then the periphery is gained. Note in passing that all centres are involved in the order from the least to the most organised. But the process is far more complex than we have stated it to be. The part of the highest centres which is highly over-unstable discharges not only "downwards," but "collaterally;" healthy collateral parts of the highest centres are discharged, and each of these collateral discharges leads to secondary discharges of the middle and tertiary discharges of the lowest centres. The middle centres are subjected not only to the primitive discharge of the part of the highest centres morbidly highly unstable, but to the induced collateral discharges of these centres. Possibly there are collateral discharges in the middle centres when they are overcome and discharged

---

(*a*) I do not pretend to be able to speak with accuracy of the exact parts which make up the middle centres. Artificial excitation of only certain convolutions produces movements; in these convolutions most large cells are found; it is from destructive lesions of fibres connected with these convolutions that descending wasting occurs, and this stops at the lowest centres. Lesions in front do not produce descending wasting into the cord; whether or not they produce wasting "descending" to the middle centres I do not know. These facts, however, are read by most physicians, not only as proving that the convolutions in question are motor, but that those in front of them are not motor; as stated I believe the latter to be also motor.

(*a*) In speaking here and elsewhere of muscular action resulting from nerve currents, I mean that there results from them "an explosive decomposition of certain parts of the muscle substance."

from above. If so the resulting convulsion will be exceedingly compound.

Taking note of the middle and lowest centres, we can state more completely the differences betwixt a case of destruction of part of the highest centres, negative lesion, and a case of high instability of part of them, positive lesion; we can in other words show more fully the nature of what we call the "double opposite" effect of negative and positive lesions. In the case of negative lesion all other healthy parts of the highest centres are left as they were, as are also the middle and lowest centres. In this case some part of the highest centres is "dead," and the rest of the nervous system is not interfered with at all. There is loss of many movements, but as these are movements of the whole body the paralysis is widely distributed—there is "weakness" all over, but no localised decided loss of power. There is compensation by the collateral parts of the highest centres, which can act on and through the intact middle and lowest centres. The compensation is very highly compound. But when there is a "discharging lesion"—a positive lesion—some part of the highest centres is "too much alive," and much of the rest of the nervous system *is* occasionally greatly interfered with; healthy collateral parts which, in the case of destruction of a part, serve to compensate a loss, are in the case of high instability of a part compelled to co-operate in an excess; each of the collateral discharges leads to "downward" discharges of the middle and lowest centres. What we called the highly compound compensation for negative lesion is in the case of positive lesion "inverted;" the co-operation in excess is highly compound; we do not say as highly compound as is the compensation in the case of negative lesion. For the parts made to "co-operate in excess" are not made to do so until their resistances are overcome; how many resistances are overcome depends on *the degree* of the primal discharge. Resistances will be considered later.

(*To be continued.*)

CATARRHAL DEAFNESS IN CHILDREN.

By GEORGE P. FIELD,

Aural Surgeon to St. Mary's Hospital.

Whilst we daily learn more of rare or hitherto comparatively little known maladies, it behoves us still ever to keep fresh in our memories the ascertained facts in connection with the every-day diseases of ordinary practice. Of catarrh of the middle ear, which it is my desire now briefly to consider, one may say that it is because perhaps the most common one of the most important causes of loss of hearing that we are liable to be called to deal with. A clear understanding of the conditions of this disease in the case of children is, moreover, especially important, not only because it is among its youngest victims that we may hope for the greatest success in treatment, but also because an early recognition of its character affords us the best chance of obviating any resultant tympanic disease, with a legion of incurable sequelæ, such as rigidity of the ossicles, and abnormal adhesions. A knowledge of what the disease is apt to lead to necessarily prepares us for that which is better than its cure—namely, its prevention.

It seems to be the popular persuasion that, in proportion to the age of a child, so does Nature exercise her *vis medicatrix*, and thus, if a child has come to suffer from deafness, as is usual from catarrh, its fond friends and parents assume that the little one will grow out of it!

Doubtless we should soon become a more or less deaf people were not the cure of aural catarrh in a large number of cases, notwithstanding the carelessness of parents, the natural work of time, for the frequency of its occurrence, in the young more especially, is amply provided for by the eccentricities of our English climate. Can we wonder that they readily take cold where a steady down-pouring rain in January and part of February is succeeded by warm summer weather, and this in March by cruel east winds and fog worthy of November and December, culminating in sleet, snow, and slush in April? What we are coming to next, and whether we are about to enter upon some new geological climatic cycle, I will not pretend to guess; but I think we may look to the weather-forecast authorities for a certain announcement of impending changeable weather! It is just the atmospheric changes that are the principal cause of aural catarrh, as a result of catarrh extending from the naso-pharynx, and, therefore, except when there is a predisposition to tympanic disease in consequence of influenza, measles, &c., one must, in the majority of cases, hope to cope with the aural disease only after remedying the condition of the naso-pharynx.

When, in consequence of inflammatory processes, there is exudation, whether mucous or serous, from the throat, the Eustachian tube is apt to become swollen and blocked, and thus rarefaction of the air in the tympanum ensues, the membrane is drawn inwards into a position of undue tension, and deafness results.

With a description of the membrane in this condition I think I need scarcely detain my audience, to whom its appearance is doubtless more or less familiar.

When fluid is present in the cavity, it can readily be discerned on inspection, the line of demarcation between it and the air above being clearly visible through the membrane. Parts only of the naso-pharynx may be subject to catarrhal inflammation. A "cold in the head" may cause simply sufficient interference with the functions of the Eustachian tube to give rise to an uncomfortable sensation of fulness in the head—conditions which in strong healthy children usually pass off with the cold. In strumous children, on the other hand, or in those that are underfed and underclothed, the cold, left to Nature to cure, may be anticipated to lead to results of a serious character.

Inasmuch as colds in the head are about the most common source of disorders of the ear, it is evidently most essential for the prevention of deafness studiously to seek to avoid them. I have spoken of the freaks of our usually dull English weather as being largely concerned in their production, but the dulness of the grey matter of many an English brain has not a little to do with their origin.

It is often interesting, though by no means satisfactory, to note the battle being carried on in the persons of prettily, but imperfectly or improperly, clothed children, between the tendencies of naturally healthy constitutions and the baleful influences of cold and exposure. Too much, or too litttle clothing for the state of the weather, draughts, damp feet, unchanged garments moist with excessive perspiration, cutting the hair too short, or wetting it at bed time—such are a few of the means by which children, not to say adults, are introduced to naso-pharyngeal catarrh, and attendant ear disease. As one cold after another is caught, the mucous membranes become permanently thickened, and a chronic catarrh is established to a great extent independent of climatic changes.

When aural catarrh does not proceed from an initial affection of the throat or Eustachian tube, but originates in the tympanum itself, deafness usually comes on at an early date, but in most cases of catarrh it is of slow growth. By degrees—perhaps at the rate of an inch or two in a twelvemonth—the hearing distance diminishes, and all that is noticed by the parents and friends of the child affected is, that for some unaccountable reason it is not so bright and keen of apprehension as it used to be. Perhaps the family censor, anxious to quicken the apparently halting brain-activities, adds a little traumatic damage to the mischief already established by administering sundry boxes on the ear; or it may be that some maiden aunt with time on her hands for the perusal of popular medical treatises comes to the conclusion and persuades the parents that the dear child's system needs more support, and that under the employment of tonics it will become as well as ever.

In the meanwhile the aural catarrh goes on, and deafness increases. At last—and, I am sorry to say, in many an instance too late—the disclosure is made that there is something wrong with the ear. The doctor then discovers that it might doubtless have been completely cured, but now there is thickening of the tympanic membrane, and a collection of inspissated mucus on its inner side, and that the ossicles are hampered in their movements. Perhaps for the first time the parents learn from him that the cuffs and blows on the head that the child has been given for its supposed inattention has only tended to increase the defectiveness of an already damaged ear.

In this connection I may remark that it is not at all uncommon at hospital to meet with cases of ear disease due to this cause alone; indeed, it is difficult to understand how any feeling short of malice aforethought can prompt anyone to correct a child in this way. Most of us, I daresay, remember the case mentioned in Holmes' "System of Surgery" of the boy who, suffering from the cerebral abscess that caused his death, had his ears boxed by his father for inattention. But recently a curious instance of the inadvisability of striking the ear, even by way of jest, came before me in the case of an actor, who, having to submit for over the space of two months to a box on the ear at the hands of a fair colleague, had developed a well-marked example of hæmatoma auris. The play was, he said, very unfairly called "Much Ado about Nothing."

The prevention of the frequent opening of the Eustachian tube, requisite for the integrity of the hearing, it must be borne in mind, is sometimes due to a habit in children of breathing through the mouth, which, in certain cases, is seemingly only an acquired trick, but, in most, is the direct result of clogging of the nostrils, swelling of the tonsils, and other hindrances to respiration caused by chronic catarrh.

The constant patency of the mouth, by impairing the function of the nasal cavities as resonators, causes the child to speak in the peculiar fashion popularly known as "talking through the nose," but which, of course, on the contrary, is not talking through the nose at all.

The open mouth, crowded teeth, and generally debilitated look of those suffering from chronic catarrh, with enlargement of tonsils, are very characteristic.

Occasionally in such children the closure of the Eustachian tube permits of the accumulation of fluid, chiefly mucus, in the tympanum, the expulsion of which allows of the restoration of hearing.

Before passing to other considerations, let me impress upon you the fact that chronic pressure on the drumhead, occasioned simply by closure of the Eustachian tube, may be the cause, not simply of temporary deafness, but of irremediable and most serious damage to the ear.

Autophony—that is, the echo of a patient's own voice—is occasionally a troublesome symptom in aural catarrh—more generally present, it is said, when a slight attack of the latter has caused one-sided deafness. The patient describes his sensations as being like those produced by speaking with one's head inside a cask.

Among the many annoyances caused by accumulation of mucus in the tympanic cavity are different kinds of noises, which result from its movement during the act of swallowing.

A sign of closure of the Eustachian tube which is not unfavourable, for the little subjects of it can nearly always be cured, is variation in the hearing distance. Sometimes the patient, after months of deafness, hears a report, like that of a gun going off, as air suddenly enters the tympanum, either because mucus within it has become absorbed, or swelling of the Eustachian tube has subsided.

There is now great improvement in hearing, owing to the more or less complete resumption by the tympanic membrane of its normal position, but in many a case, unless proper treatment is adopted, the hearing is suddenly lost again.

In children damp weather may, year after year, bring on deafness, and the more frequently this occurs, so much the more likelihood is there of chronic permanent injury to audition. The continued presence of mucus in the tympanum no doubt may lead, not only to thickening of its mucous membrane and other changes, but also to purulent discharge, which not infrequently comes on without any apparent cause.

When of recent origin, simple aural catarrh in children yields readily enough to constitutional remedies, astringent applications to the back of the throat, and the use of Politzer's air-bag. This air-bag has, no doubt, served for the cure of hundreds of little patients, who, without its aid, would have become irremediably deaf.

During the act of swallowing the orifice of the Eustachian tube is opened, and, as it is then that the bag is compressed, air is forced through the nose into the throat, and thence through the obstructed Eustachian tube into the tympanum. The loud, explosive sound heard as air reaches the drum-head is usually at once followed by considerable alleviation of the deafness. Even those who have had long experience in the treatment of aural disease are sometimes astonished at the rapidity with which loss of hearing due to obstruction of the Eustachian tube disappears on the employment of Politzer's bag, a single application being sometimes all that is required. I have never yet seen any ill effects from its use in the case of children. When, in adults, the bag has failed to be of service, one may find it advisable to resort to the use of the Eustachian catheter; but this in children I should never recommend, for the simple reason that they will not submit to it!

As sudden inflation of the tympanic membrane is liable to occasion its rupture, care must, of course, be taken that it be not effected with too great force. In connection with Politzer's bag—which is conveniently of the capacity of six ounces—I find it well to employ Allen's nasal pad, as this dispenses with the insertion of the end of the tube within the nostrils, to which both children and ladies evince a decided objection.

In respect to the use of Politzer's process, there is one caution necessary—viz., that one may avail one's self of it too frequently. Valsalva's method of charging the tympanum with air—that is, to hold the nose and blow while the mouth is kept closed, when constantly employed by patients affords less and less relief, and may become worse than useless, and the same is true of the too-often repeated use of the bag, as when it is applied by a patient to himself three or four times a day. It suffices to open the occluded Eustachian tube only now and then—say, twice a week—so as to ventilate, after a fashion, the tympanic cavity. By this means the tube is soon rendered permeable, especially if an astringent be applied twice daily with a bent brush to the back of the throat, such as one drachm of the tincture of perchloride of iron to an ounce of water, or glycerine and tannin, and water in equal parts. Even the employment of the nasal douche, or the sniffing up through the nostrils of alkaline solutions, may prove injurious to the hearing by occasioning the introduction of fluid into the tympanic cavity.

For the constitutional treatment of aural catarrh, mild purgatives, cod-liver oil, the iodide and phosphate of iron, or steel wine may be administered with good effect in various cases.

By the simple methods I have described the majority of cases of catarrhal deafness in children can be rapidly cured; but in some instances the removal by guillotine of portions of enlarged tonsils is requisite. Of necessity, as healthy surroundings exercise a powerful influence for good in every catarrh, damp and ill-ventilated rooms, and wet and smoky localities must be shunned by sufferers from aural catarrh, and plenty of outdoor exercise in fine weather and tepid baths should be recommended. Bathing and diving, whether in the sea or in fresh water, should not, however, be attempted unless the ears are well closed with plugs of cotton-wool. In patients with whom all local treatment fails, a residence in a dry, mountainous region will generally prove highly efficacious in lessening catarrhal secretion.

I have now, I think, said all I intended to state with respect to catarrhal deafness in children. The subject, I admit, is well worn; but, at the same time, it is scarcely possible for the attention of the profession to be too frequently directed to it, seeing how large a number of children suffering from the disease are, through the lack of timely advice, allowed to remain deaf until they become too old for treatment to avail them anything.

Clinical Records.

ST. MARY'S HOSPITAL.

Traumatic Diffuse False Aneurism—Amputation—Recovery.

Under the care of A. T. NORTON.

A. B., an agricultural labourer, on jumping from a hay-cart, fell upon the prongs of an iron rake which rested upon the cart. One of the prongs entered the right thigh on the inner side close to Hunter's canal, and broke off. The piece was removed by a fellow-labourer, and a strong gush of blood followed. Fortunately, the St. John's Ambulance Association lectures had been delivered in the neighbourhood, and methods of arresting hæmorrhage were not altogether unknown among the agricultural peasants. A large pad of tobacco was placed over the wound and a handkerchief bound tightly over the spot. The bleeding was stopped, and the man carried to the local infirmary. From there he was transferred on the third day to St. Mary's Hospital. When admitted, I found the size of the right thigh 26 inches round, as compared with the left, 16 inches round. The swelling dilated slightly in all directions with the heart beat, and on the inner side, along the course of the vessels, was a well-marked thrill, for some inches above the swelling; the injured leg was much colder than the other, but a slight pulse could be felt in the posterior tibial artery. It was evident that a false diffuse aneurism existed, and the thrill in the course of the vein suggested injury to the vein as well, though I am inclined to think that such a thrill might exist as a result of the pulsatile compression of the vein by the tumour without itself being injured. The pulse in the posterior tibial artery would have led one to believe that it was not the main trunk of the femoral artery injured, but some large branch, and the fact that the swelling was not increasing in size led to the same conclusion; but against this it must be understood that the injury to the vessel had been done three days previously, and collateral circulation would be established in that time sufficient for the development of a small pulse in that artery.

It was sufficiently clear that we had a diffuse false aneurism of traumatic character to deal with, and the principle of treatment was to ligature the artery above and below the wound; but the exact seat of the injury was not evident, because the prong might have penetrated the limb obliquely. I decided to cut down upon the vessel in the lower part of Scarpa's triangle and dissect it in its course to the seat of injury. I made an incision four inches in length over the inner border of the sartorius in the lower part of the triangle, and found the artery in the usual way, and then dissected downwards through the inner wall of Hunter's canal. I now compressed the artery to see the effect on the blood tumour, and found that the injury must be below Hunter's canal, because compression caused complete loss of pulsation in the aneurism. Continuing the dissection into the upper part of the popliteal space, I came upon the blood clot, and an immediate gush of blood followed. The Esmarch cord was applied, and the operation continued. About half an inch below Hunter's canal the artery was found to be completely severed by a laceration, and the vein ripped open, but not severed. The question arose in my mind whether there would be any chance of a successful result by ligature alone; but it is well known that when the vein is injured at the same time with the artery complications arise which almost invariably necessitate secondary amputation, and the result is usually death.

In this case, in addition to the injury of both vessels, there was extensive separation of the muscles by the blood clot, the whole of which cavity would doubtless suppurate, and on this account I decided to amputate at once in the middle of the thigh. The rest of the history of the case is that of an ordinary amputation. The temperature never rose above 101°, the wound healed mostly by the first intention, and the patient is at the present time in a convalescent state.

Germany.

[FROM OUR SPECIAL CORRESPONDENT.]

THE GERMAN HYGIENIC EXHIBITION.

The Imperial Health Office.—The jurors appointed to award the prizes, the president of whom is Excellenz von Langenbeck, with Billroth as deputy, decided that no State or city authorities should be eligible for the Empress's medals. As exhibitions are for the encouragement of private enterprise, the decision seems to have been a reasonable one. Without such a decision to guide them they could scarcely have avoided awarding one to the Imperial Health Office, as being second to none in furthering the objects of the Exhibition. The health office has its quarters in what is called a pavilion, an erection to which the name of barracks would have been more appropriate. This building is situated on the northern limits of the Exhibition grounds, in the immediate vicinity of the music hall, and of a bakery in full work. The structure is divided in the midst by a corridor, the part on the one side of the corridor forming a complete laboratory for a public analyst, whilst the other half is devoted to the investigation of infectious diseases and disinfectants. Upon entering the latter part the eye is met by long rows of "pure" cultivation preparations of those vegetable parasites that are supposed to be the originators of tubercle, erysipelas, glanders, septicæmia, &c., the micrococci of pus, milk, yeast, &c. The peculiarity of the Imperial Health Office's "pure" cultivations is that they are carried out on a solid field of growth. A solid is considered preferable to a liquid field, for the reason that in the former case, when a different fungus from the one under cultivation alights thereon, it affects only the spot on which it alights. Here it can be detected, and its presence being known it is without disturbing influence on the success of the experiment. If the cultivation soil, on the other hand, be liquid, there is nothing to prevent different forms of fungi becoming inextricably intermingled. The principal cultivation soils are three in number—1st. Cooked potatoe; upon it are cultivated the yeast fungus, the bacillus of green pus, and the micrococcus prodigiosus. The second is nutrient gelatine, made in a particular manner from gelatine and fowl broth; this is of a beautiful straw yellow colour, and absolutely transparent. This soil has one disadvantage, however, in becoming liquid at elevated temperatures. The third form is sterilised blood serum. The mode of sterilisation will not be uninteresting. It is well known that the perfect or developed forms of bacilli and micrococci are destroyed at even a moderately low temperature, but that the spores of these require a much higher temperature for their destruction—a temperature that would render the blood serum a thick, opaque, coagulated mass. The developed forms are first destroyed at a low temperature of 135°F.; the preparation still containing the permanent spores is then put into the incubation apparatus, where they develope.

These in their turn are destroyed at 135°F. These processes go on—development of germs and destruction of the developed forms—until a preparation is obtained transparent and quite free from germs. Upon this, bacilli from the bodies of animals grow freely. Koch's bacillus tuberculosus may be seen growing on the surface of serum thus sterilised as a dry white scale, distinguishable from other fungi by the naked eye. The bacilli of glanders for the discovery of which we are likewise indebted to the Imperial Office, are seen upon serum as a yellow translucent coating, which, later on, become whitish. By the naked eye they are recognisable from other forms from their forming a brownish coating when cultivated upon the potatoe. Preparations showing the effects produced by the various bacilli at the various stages of development are shown, also the various effects on different classes of animals. Some of these diversities of effect are curious; thus, whilst in rabbits the kidneys have a special affinity for the bacillus tuberculosus, in guinea pigs the liver and spleen are most affected. With regard to the various organisms that affect milk, the bacillus that turns milk sour at temperatures above 68°F., is shown (not identical with the oïdium lactis), also the micro-organism that produces butyric acid, and also that which turns milk blue. The bacillus of green pus, transferred to milk and a violet bacillus are exhibited, both organisms that precipitate the albumen of milk and peptonise it. Characteristic micrococci from vaccine vesicles and variola are also exhibited, but they do not represent the virus of the disease, as inoculation of them has had only negative results. As may be supposed almost every imaginable kind of apparatus is on view. One is a contrivance for automatically shutting off the gas when the flame has accidentally gone out. One noticeable feature about the apparatus is the great use that has been made of nickel for electro-plating the various articles. Another is the spirit of economy that has ruled this department, as shown in the simplicity and inexpensiveness of the apparatus exhibited, no articles being more showy, complicated, or expensive than their purpose has required.

◆

We regret to learn that Surgeon Lewes has been attacked with cholera whilst in the discharge of his duties at Cairo.

A microscopical examination of the Nile made on Saturday last shows that the water which the inhabitants are consuming is teeming with bacilli.

In view of the possibility of an outbreak of cholera, the Paris Municipal Council have voted 480,000 francs for the erection of wooden buildings in the bastions of the fortification to serve as hospitals. Eventually these will be used for patients suffering from other contagious diseases.

We understand that Surgeon-General Hunter, who has been sent out to Egypt by Her Majesty's Government in medical charge during the cholera epidemic, finds his duties of the most arduous and anxious nature, every spot proving a focus of infection.

The War Office has sent to Egypt fourteen young medical men whose energy and intelligence has recommended them to special consideration for the purpose of helping the military authorities to deal with the cholera epidemic. Sir Joseph Fayrer has practically had the selection in his hands, and each such officer is to receive £100 a month besides travelling expenses.

THE BRITISH MEDICAL ASSOCIATION.

[From our Special Correspondent.]

At length the day has come, the advent of which many good Liverpudlians have looked forward to with much expectation, not, perhaps, unmixed with some anxiety that the many "events" of the day should come off with becoming *éclat*. That the fifty-first (Liverpool) meeting of the British Medical Association will be a success, and a great one, is no longer doubtful. I should be afraid to say how many hundreds of visitors we already have in town, but I do know that every room in most of the leading hotels is already engaged. The first public event in connection with the meeting was Divine Service in the Pro-Cathedral. A large number of members availed themselves of the opportunity alike of performing an act of devotion and of making acquaintance with the plain-looking edifice in Church Street, within the interior of which are to be seen an exceedingly ugly east window; a reredos of dark oak, to my non-artistic eye as handsome as the window is the reverse; a brand-new episcopal throne and lectern that is universally admired; and, finally, the manly proportions of the bishop, who is "not ashamed to say that he has a son a doctor." The sermon to which they listened was appropriate to the occasion, and, although the preacher cannot lay claim to many of the graces of oratory, there was a certain manliness about both himself and the sermon that went far to make up in the minds of his hearers for jerky utterances, and perhaps, if the truth must be told, a slight ungainliness of manner.

NEW HOSPITAL FOR WOMEN.

A not unimportant event, although not directly connected with the meeting, had been timed for the opening day so that some distinguished medical men from a distance would have an opportunity of gracing it by their presence. I refer to the formal opening of the New Hospital for Women. You have already referred in your columns to the acquisition of premises by the New Hospital authorities, and to the alterations that were being made in order to fit them for their new purposes. I have now to say that no labour and no expense have been spared to render them as perfect, from a sanitary point of view, as the science of the day permits of. The drainage has been thoroughly overhauled, and it was not a little that was required in this direction; the walls have been first papered, and then covered with four coats of paint. The floors have been freshly planed, stained, and varnished; and in the way of ventilation, Gibbs's patent ventilating shafts bring pure air from the exterior, whilst exit ventilators in the chimneys carry off the impure. The first thing in the order of ceremonies was an elegant repast provided by the committee. As the accommodation was limited, only about eighty invitations could be issued, and the event proved how unsafe it would have been to send them out broadcast, as there were but few refusals. After the lunch the guests retired to a large and beautiful room on the first floor to meet the subscribers who had been invited to be present at the opening. Here the Countess of Sefton, the patroness, declared the hospital open, and Sir T. Spencer Wells gave an able address. When the name of this distinguished surgeon is mentioned the most rabid caviller at special hospitals must be dumb.

But I must proceed to the more special business of this communication. Before the first general meeting of the Association, at 3 o'clock, I took a rapid survey of the Museum.

THE MUSEUM.

On approaching the entrance door of this apartment the visitor first observes to the left of the doorway a large show-case of the well-known firm of Evans, Sons and Co., Liverpool and London, and on the other side that of Mellin's Infants' Food Company. It may be observed of this food, that although it has been known and appreciated as perhaps the most perfect of infants' food next to milk, it has not become well-known till quite recently. On passing through the doorway a striking spectacle meets the eye. Imagine a room 300 feet long and 25 feet wide, lighted from above. Imagine again side-tables covered with crimson felt running nearly the whole length, and another long table running down the centre, and all decked out with drugs and pharmaceutical preparations of every conceivable, if not inconceivable, kind, enclosed in sparkling glass, and instruments and appliances, the exhibits of the various firms vying with each other in ingenuity, elegance, and skilfulness of workmanship.

Immediately opposite the doorway is the large and handsome stand of Parke, Davis, and Co., Detroit, containing samples of all the new drugs and preparations for which in a short time they have made themselves noted in Cisatlantic regions. A novelty of theirs that is like to come into use is a gelatine capsule, consisting of a hollow body part and a movable cap, intended for the administration of powders, &c., by the mouth, and for powders and ointments *per rectum*, or for the cavity of the uterus. Next to this stand, going south, is that of Syme and Co., of Liverpool, a firm well known in this city, and with a reputation not confined to it. Going further south, the visitor comes to the stand of Savory and Moore, London, and the Montserrat Lime Juice Company. Messrs. Arnold and Sons, London, occupy a table that reaches across the south end of the hall. On the east side, commencing from the south, the stall of Newbery and Sons contains some well-made emulsions of cod-liver oil. Near them is that of Mackay, Mackay, and Co., London; Richardson's, Leicester; Wyeth Brothers; Burroughs, Wellcome, and Co., the latter containing, amongst other things, samples of Hazeline, Beef and Iron Wine, Kepler's Malt Extract, &c. North of the doorway on the same side come the exhibits of Clay and Abraham, Liverpool; Corbyn, Stacey, and Co., and others. On the west side, again, beginning at the north, is the Maltine Manufacturing Co., exhibiting the now well-known Carnrick's Beef Peptonoids; then Southall, Sons, and Barclay. The centre table is occupied by, amongst others, Weiss, J. Wood, W. Wood, Krohne and Sesemann, Aitken and Co., White and Wright, Meyer and Meltzer, and many others. Downstairs, in a room on the west side of the basement corridor, are some of the larger exhibits. Amongst these were noticed a complete suite of consulting-room furniture in light oak and morocco, hospital beds with spring mattresses. Billington Brothers, Duke Street, Liverpool, exhibit some very well made and economical beds of this description; and the patent spring beds of Chorlton and Dugdale, such as are supplied to the Hospital for Women, are also on view here.

Adjourning now to the Hall of the College, we find a room not very large in itself, but so arranged with galleries as to be capable of seating something over 2,000 people. Here, some little time before the hour appointed for the opening public meeting (3 p.m.), members began to assemble, either congregating in groups, or disposing their forces for the struggle that was known to be coming on the proposed alteration of by-laws; or, in the case of strangers, taking their seats, and gazing about with that languid curiosity that marks the man who has some minutes to while away in a strange place, and who, fixing his eye on a group, wonders whether he shall by-and-by know who this or that individual in it may be. But the hour of meeting approached, and the hall filled up, and members took their places, and it became noticeable to an observant onlooker, as a neighbour remarked to me, that upon the whole they were "a respectable-looking body of men, few of whom, as far as outward appearances went, would not be ornaments to a Board of Guardians."

But I am trespassing. I must, moreover, tear myself away from this first meeting, that, promises to be anything but a "dead-and-alive" one, and not neglect other duties, even although they may not be so attractive as a general business meeting of the B. M. A.

With regard to the arrangements for the remainder of the week, both those relating to business, science, and pleasure are as complete as hard work can make them. To begin with the local committee. The raising of funds has of course been the first requisite, and in this the hon. treasurer, Mr. W. M. Banks, has already succeeded in raising a sum which is considered will be amply sufficient to meet every demand. All the sub-committees have worked with a will and a success corresponding to it. A considerable number of distinguished foreign physicians and surgeons were invited to attend as the guests of the local committee, but only a few were able to avail themselves of the invitation. No doubt the time at which the meeting is taking place has had a great deal to do with refusals, as no foreign Universities close their session before the 31st of July, and many not till about the 15th of August. In consequence of this, but few foreign professors have been able to leave their classes in time to take part in the meeting. Besides some Americans, the only foreign gentlemen who have announced their intention to be present are Professors Binz, of Bonn, Snellen, of Utrecht, and Loven, of Stockholm.

The subjects for discussion in the various sections are important, and will prove very attractive.

The special entertainments include a *soirée* given by the local committee in the three adjoining buildings, which will be thrown into one—the Brown Museum, the Picton Reading Room, and the Walker Art Gallery. These imposing edifices, which were erected at a cost of not less than £75,000, contain much that Liverpool boasts of in the way of art, whilst science, in the shape of a magnificent natural history collection, is worthily represented. These buildings contain the Derby Museum, presented by the twelfth Earl of Derby to the borough of Liverpool, the Mayer Collection of Antiquities, collected by the donor, Mr. Joseph Mayer, at a cost of £50,000 in money and the labour of a lifetime, the Free Public Library, and the Collection of Pictures and Statuary in the Art Gallery.

The following is the complete Programme of Proceedings:—

TUESDAY, JULY 31*st*.

The Session will be commenced by a short service and sermon by the Bishop of Liverpool, in the Pro-Cathedral, at 10.30 a.m.

At 12, meeting of the Committee of Council in the Committee Room.

At 12.30 p.m., meeting of the Council of 1882-83.

At 3 p.m., First General Meeting: Report of Council. Special business: Proposed Alteration of Bye-laws; and any other business.

At 8.15 p.m., the adjourned General Meeting will be held, when the President will deliver his address. The Annual Report of Council and other business will then be taken. Tea and coffee will be served after the meeting.

WEDNESDAY, AUGUST 1st.

At 9.30 a.m. there will be a meeting of Council, 1883-84.

At 11 a.m.—Second General Meeting, when an Address in Surgery will be delivered by Reginald Harrison, F.R.C.S., Surgeon to the Liverpool Royal Infirmary.

In the Surgical Section

the following subjects have been selected for discussion:—1. Mr. Clement Lucas will open a Discussion on Surgical Diseases of the Kidney, and the Operations for their Relief. 2. A Discussion on the Treatment of Intestinal Obstruction by or without Operative Interference will be opened by Mr. Rushton Parker.

The office-bearers in this Section are:—*President:* Edward R. Bickersteth, F.R.C.S. *Vice-Presidents:* W. Hargreaves Manifold, M.R.C.S.; W. Mitchell Banks, F.R.C.S. *Secretaries:* Rushton Parker, M.B., F.R.C.S., 61 Rodney Street, Liverpool; Edmund Owen, M.B., F.R.C.S.

From 1.30 to 5 p.m.—The various Sections will meet for papers and discussion.

At 5 p.m.—Annual Meeting of the Irish Graduates' Association; after which,

At 6.30 p.m.—The annual Graduates' Dinner will take place at the Adelphi Hotel.

At 8.30 p.m.—*Soirée* in the suite of rooms forming the Arts Gallery, the Picton Reading-room, and the Free Library, by the President and Local Committee. To this ladies will be invited.

THURSDAY, AUGUST 2nd.

At 9 a.m.—Meeting of Committee of Council.

At 10 a.m.—The Third General Meeting will be held, to consider proposed Alteration in the Articles of Association. An adjournment for luncheon will take place at 1 o'clock.

From 2 to 5 p.m.—The Sectional Meetings will be resumed.

At 6.30 p.m.—Public Dinner in the Philharmonic Hall.

FRIDAY, AUGUST 3rd.

10 a.m.—Fourth General Meeting, at which an Address in Pathology will be delivered by Charles Creighton, formerly Demonstrator of Anatomy in the University of Cambridge.

In the Pathological Section

the following discussions will take place:—

1. On Micro-organisms in Disease. To be opened by Dr. Dreschfeld. Dr. Shingleton Smith and Dr. P. M. Braidwood will take part in the discussion.

2. On Micro-organisms in Typhus. To be opened by Drs. Mott and Blore. Drs. Davidson and Barron will take part.

3. On the Pathology of Dropsy. To be opened by Dr. Lauder Brunton. Drs. Saunby and Churton will take part.

4. On Chronic Inflammations of Bone. To be opened by Mr. Charters J. Symonds.

5. On Primary Growths of the Urinary Tract. To be opened by Mr. Frank T. Paul. Mr. Roger Williams will take part in the discussion.

Cirrhosis and allied conditions of the Liver will be brought forward, should time allow.

The office-bearers in this section are:—*President:* T. H. Green, M.D. *Vice-Presidents:* E. H. Dickinson, M.D.; Joseph Coats, M.D. *Secretaries:* Frank Thos. Paul, F.R.C.S., 44 Rodney Street, Liverpool; James F. Goodhart, M.D.

At 2 p.m., the concluding General Meeting will be held.

At 8.30 p.m., a *Soirée*, given by the Mayor and Corporation of Liverpool, will be held at the Town Hall. To this ladies will be invited.

THE SECTIONS.

Besides the Sections mentioned in the foregoing Programme there will be eight others, in which no opening address will be delivered, but in which various subjects will be brought forward for discussion:—

Medicine.—1. A Discussion on Aphasia will be opened by Professor Gairdner of Glasgow. 2. A Discussion on the Causes and Consequences of Abnormal Tension in the Arteries will be opened by Dr. Broadbent. 3. A Discussion on the Nature of Purpura will be opened by Dr. Stephen Mackenzie.

The following are the office-bearers in this Section:—*President:* John Cameron, M.D. *Vice-Presidents:* Thos. R. Glynn, M.D.; Frederick T. Roberts, M.D.; Dyce Duckworth, M.D. *Secretaries:* Richard Caton, M.D., 18a Abercromby Square, Liverpool; Byrom Bramwell, M.D.

Obstetric Medicine.—Special discussions are expected to take place in this Section on the following subjects:—1. Total or Partial Extirpation of the Uterus for Malignant Disease. Introduced by papers by Professor Schroeder (Berlin) and Dr. Wallace. 2. On Operative Treatment of Uterine Fibromata. Introduced by papers by Mr. Knowsley Thornton and Mr. Lawson Tait. 3. On Metria (so-called Puerperal Fever). Introduced by papers by Dr. Atthill and Dr. Thorburn. 4. Porro's Operation. Introduced by a paper by Dr. Clement Godson.

The following are the office-bearers in this Section:—*President:* W. M. Graily Hewitt, M.D. *Vice-Presidents:* John Wallace, M.D.; David Lloyd Roberts, M.D. *Secretaries:* John E. Burton, L.R.C.P., 64 Rodney Street, Liverpool; W. C. Grigg, M.D.

Public Medicine.—Four topics have been selected for discussion in this Section.

1. Directions in which Public Health Law might be advantageously Amended or Extended. Mr. Charles Wills will read a paper on the general subject. Mr. Ernest Hart will read one on the Advisability of an Extension of the Law for the Regulation and Registration of Plumbing in Houses. Dr. William Carter will open a discussion on these papers.

2. Quarantine. Dr. Imlach will read a paper on Quarantine.

3. Disposal of Town Refuse. Dr. Goldie and Dr. E. Whittle will read papers on this subject.

4. Etiology of Diphtheria and Autumnal Diarrhœa. Drs. Alfred Carpenter, H. J. Alford, and E. F. Willoughby will read papers on Diphtheria, and Mr. M. D. Makuna one on Autumnal Diarrhœa, and Captain Douglas Galton, C.B., F.R.S., one on Hospital Construction.

The office-bearers in this Section are:—*President:* T. P. Teale, M.B., F.R.C.S. *Vice-Presidents:* William Carter, M.D.; W. Honner Fitz-Patrick, M.D. *Secretaries:* F. Pollard, M.D., 52 Rodney Street, Liverpool; George Goldie, M.D.

Anatomy and Physiology.—Mr. Lennox Browne will exhibit on the magic-lantern screen, by means of oxyhydrogen light, a series of photographs of the Larynx and Soft Palate in the production of various Musical Tones.

Afterwards, Mr. Emil Behnke, from whom the pictures have been taken, will exhibit his Larynx to the members present, so as to demonstrate practically the physiological facts illustrated by the photographs.

Mr. C. B. Lockwood will show an anatomical specimen illustrating the use of the Fossa at the Lower End of the Fibula.

Dr. E. H. Jacob will show (1) Photographs of Chick Embryos; (2) a Portable Polygraph.

Dr. Francis Warner will give a Demonstration of an Apparatus for obtaining Graphic Records of the Movements of Fingers, Hands, Head, &c., and enumerating them and their combinations.

Dr. John Harker will show a sketch of Abnormal Hands and Feet in the case of an Infant.

Mr. Sibley Hicks will exhibit a series of Embryos to illustrate the development of the Chick.

Mr. G. Padley will exhibit (1) a Dissection of an Abnormal Distribution of the Arteries in the Fœtus; (2) Abnormal Distribution of the Arteries of the Arm.

Dr. R. Norris will exhibit his Museum of Photographs of the Blood.

Dr. C. W. Cathcart will exhibit a new form of Ether-freezing Microtome.

Dr. W. Darling will exhibit a specimen of United Fracture of the Atlas and Odontoid Process of the Atlas.

The office-bearers in this Section are:—*President*. Professor E. A. Schäfer, F.R.S. *Vice-Presidents:* William Stirling, M.D.; Richard Norris, M.D. *Secretaries:* James Barr, M.D., 1 St. Domingo Grove, Everton, Liverpool; A. W. Mayo Robson, F.R.C.S.

Psychology.—In this Section the following special subjects have been selected for discussion:—1. The Employment of the Insane, introduced by Dr. Yellowlees. 2. Bone Degeneration in the Insane, introduced by Dr. Wiglesworth. 3. Cerebral Localisation in relation to Psychological Medicine, introduced by Mr. W. Bevan Lewis. 4. General Paralysis, introduced (if time permit) by Dr. W. J. Mickle.

The office-bearers in this Section are:—*President:* T. L. Rogers, M.D. *Vice-Presidents:* G. H. Savage, M.D.;

D. Yellowlees, M.D. *Secretaries:* G. E. Shuttleworth, M.D., Royal Albert Asylum, Lancaster; W. Julius Mickle, M.D.

Ophthalmology.—Three subjects have been selected for discussion in this Section:—1. On Tests for Colour-sense and for Acuteness of Vision, with special reference to Schools and Sailors; opened by Dr. W. A. Brailey, followed by Dr. Snellen (Utrecht). 2. On the Use of the Magnet in Ophthalmic Surgery; opened by Mr. Simeon Snell, followed by Dr. W. A. McKeown. 3. On the various methods of Treatment for Sloughing Ulcer of the Cornea, with especial reference to Incision and Scraping; opened by Mr. T. Pridgin Teale, followed by Dr. Little.

The office-bearers in this Section are:—*President:* T. Shadford Walker, M.R.C.S. *Vice-Presidents:* E. Nettleship, F.R.C.S.; C. E. Fitzgerald, M.D. *Secretaries:* E. A. Browne, M.R.C.S., 86 Bedford Street, Liverpool; C. E. Glascott, M.D.

Diseases of Children.—Three special subjects have been selected for discussion:—1. Dr. T. Barlow will open a discussion on Rheumatism and its Allies in Children. 2. Dr. Ballard: On the Etiology and Pathology of Summer Diarrhœa. 3. Mr. Morrant Baker: On Acute Epiphysal Necrosis and its Consequences.

The office-bearers in this Section are:—*President:* Samuel Jones Gee, M.D. *Vice-Presidents:* M. G. B. Oxley, M.D.; T. R. Jessop, F.R.C.S. *Secretaries:* H. G. Rawdon, M.D., 42 Rodney Street, Liverpool; H. Ashby, M.D.

Otology.—Discussions will take place on the following subjects:—1. A discussion on the more serious aspects of Chronic Purulent Inflammation of the Middle Ear will be introduced by Dr. W. Laidlaw Purves. 2. A discussion on the various forms of Artificial Tympanic Membrane, and their Comparative Value, will be introduced by Dr. F. M. Pierce.

The office-bearers in this Section are:—*President:* G. P. Field, M.R.C.S. *Vice-Presidents:* Edward Woakes, M.D.; C. Warden, M.D. *Secretaries:* Thos. Barr, M.D.; R. Williams, L.R.C.P., 82 Rodney Street, Liverpool.

EXCURSIONS.

SATURDAY, AUGUST 4th.

The following excursions have been arranged:—1. Excursion to Conway and Llandudno. By steamer (if the weather be suitable; if not by train), leaving Liverpool soon after 9 A.M., arriving at Conway about noon. The visitors will be entertained at lunch (in the old Banqueting Hall of Castle) by the members of the North Wales Branch. They will then proceed to Llandudno by train; will leave there between 6 and 7 P.M., arriving in Liverpool between 9 and 10 P.M. Number limited to 150.—2. Excursion to Chester and Eaton Hall. Leaving Lime Street station at 9.30 A.M., arriving at Chester about 10.30; proceeding at once to the river Dee, up which the visitors will be taken by steamer and barge to Iron Bridge, where light refreshments will be provided. By kind permission of the Duke of Westminster, the hall, gardens, and park will be open to the visitors. The return to Chester will be arranged so as for dinner to be served at the Grosvenor Hotel at 4 P.M. The members will thus have the evening free for an inspection of the old city, or for their return home by any convenient train. There will be no limit as to numbers.—3. Excursion to Southport and Blackpool. By train from Tithebarn Street Station soon after 9 A.M., for Southport, where the members will be entertained at breakfast by the local medical profession; thence, at 1 P.M., by steamer to Blackpool, where dinner will be given by the directors of the South Shore Hydropathic Institution. The return from Blackpool will be arranged to take place by train early in the evening. The number will be limited.—4. Excursion to Lancaster. By train from Liverpool at 10.5 A.M., arriving at Lancaster 11.40 A.M. A limited number of visitors (30) will be entertained at lunch by the members of the medical profession of the city, who will also kindly provide carriages, and show their guests through the Castle, the Royal Albert Asylum, the County Lunatic Asylum, and other places of interest. The well-known watering-place, Morecambe (ten minutes' railway journey), is within easy reach. There the visitors can dine, and thence return by train, so as to arrive in Liverpool soon after 8 P.M.—5. Mr. Bickersteth's River Excursion. By steamer, leaving the landing-stage about 10 A.M., proceeding seawards for some distance, so as to give visitors a view of the coast; on its return, visiting some of the new docks, and then steaming up the river for some miles to Eastham, or Runcorn. This will be a half-day excursion terminating about 2 P.M. Further particulars may be obtained from Mr. Richard Williams (82 Rodney Street) for the Conway Excursion; Mr. Warburton (114 Princes Road, Liverpool) for the Chester Excursion; Mr. George Walker (43 Rodney Street) for the Southport and Blackpool Excursion; and Dr. Hopper (63 Rodney Street) for the River Excursions.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 1, 1883.

THE BRITISH MEDICAL ASSOCIATION MEETING.

If progress in medicine is measurable by the effort made to advance our knowledge of disease by discussion, then ought the annual meetings of the British Medical Association to be taken as indicating very considerable improvements in science and practice. Judging from the imposing programme of papers to be read and discussions to be held this week at Liverpool, it is reasonable to anticipate important results from the gathering of 1883; and such a conclusion will very likely be justified by the history of the future. There are very many subjects of which the information we possess has been derived from numerous observers, whose investigations have oftener than not been suggested by the work of others rather than initiated by themselves. Indeed it may almost be said that no important discovery or improvement has been wholly the achievement of one independent authority, but has slowly and gradually arisen out of the accumulated productions of many minds, each helping forward a little further towards the point of perfection, and each essentially animated by the experience gained through preceding researches of other investigators. In surgery as well as in medicine, in the associated sciences as well as in the practical departments, and equally also in the realms of purely speculative science is this the case; and it would not be going too far to assert that the impetus given to modern thought and modern progress has mainly originated at such conventions as that which gives its title to the present article.

The list of subjects to be treated is rich and extensive. It includes many that are well worthy of the wider attention and study that will be given to them by those whose inquiry will be stimulated by the authors who have already entered on the path of discovery; and not a few, we take it, who go to listen will leave resolved to help in elucidating the problems brought to prominent notice. The Section of Medicine will be the arena of discussions on aphasia, on the causes and consequences of abnormal tension in arteries, and on the nature of purpura. Professor Gairdner, of Glasgow, will open the first of these questions; and among the members who have signified an intention to speak also on it are Drs. Hughlings Jackson, Broadbent, Ferrier, Drummond, Ross, Wahltuch, Althaus, and Thudichum. Dr. Broadbent will open the discussion on abnormal arterial tension, and among those who succeed him will be Drs. Milner Fothergill, W. F. Wade, B. Foster, Mahomed, and Eddison. On the subject of purpura, to be introduced by Dr. Stephen Mackenzie, several recognised authorities on skin affections will speak.

In the other sections, of which not less than ten in all are arranged, special subjects have been announced for discussion; and each one will educe experiences that will be of paramount service in the way of instruction and advice. The operative treatment of renal diseases, which Mr. Clement Lucas is down to introduce, will probably lead to a most interesting and valuable discussion, and it will serve to illustrate also the considerable strides made in this branch of surgery within the past few years. Since it came before the International Congress in 1881 a good deal has been done in the way of extending the experience of operators as to the class of cases favourable to operative interference, and it is not unlikely that yet more useful suggestions may be forthcoming as a result of the approaching discussions. In the Obstetrical Section Porro's operation is very naturally to be considered, for even since the last meeting of the Association something has been gained to add to what could then be said in defence of this heroic proceeding in desperate circumstances. In the same section an interesting and important discussion is likely to result on the papers to be read by Drs. Atthill and Thorburn on Puerperal Fever; and Mr. Burton's "Plea for more persevering Treatment of Uterine Cancer in Cases in which Operation by Removal is impracticable" should bring out the combined experience of gynæcologists.

Some estimate of the importance and proportions of the present congress may be formed from the fact that no less a number than two hundred and thirty-five papers are down for reading, distributed over the ten sections. All of these, we may presume, present some point of particular interest or obscurity; and thus will be the means of explaining hitherto imperfectly understood details, or of exciting discussions in explanation from others. Dr. Lauder Brunton selects the familiar topic of "Headache" for a paper in the Section of Medicine, and it is probable that the difficulties presented by many intractable forms of this obstinate affection will receive a new interpretation at Dr. Brunton's hands. In the same section Dr. Drummond, of Newcastle-on-Tyne, will read notes on an unusual case of locomotor ataxy, a case which, having recently had an opportunity of examining it, will, we feel sure, excite an unusual degree of interest. The patient, a man, can date the disease but ten months back, and it exists in him already in a most exaggerated form. This section, however, is especially rich in promise of absorbing interest, and some of the subjects to be debated, like early tapping in dropsy (Dr. Austin Flint, New York), the newer doctrines of phthisis (Dr. C. E. Drysdale), inhalation for lung affections (Dr. Hassall), percussion in diagnosis (Dr. Sansom), hay fever (Dr. Thudichum), &c., &c., will provoke a most valuable addition to our knowledge.

The Section of Surgery is also rich in valuable contributions. Mr. Southam, of Manchester, raises the question of treatment in cases of aneurysm, in connection with an instance of femoral aneurysm injected with fibrin ferment, and subsequent ligature of the external iliac artery. Mr. Norton reads a paper on a case which is of the highest suggestive value, in which excision of the upper jaw was performed on account of melanotic cancer of the antrum. Mr. Noble Smith invites criticism on his method of treating lateral spinal curvature; and Mr. Walter Whitehead will present a further series of twenty-five cases of excision of tongue after his own method by aid of scissors. Mr. Morrant Baker will advocate removal of this organ by median division; and it is probable that the discussion naturally to be expected on the merits of various modes of operation, notwithstanding it has already more than once taken place, will help to settle the question on a firm basis for future guidance.

No less than five communications bearing on the surgery of the intestines are promised, and include description of a new clamp for enterectomy (Mr. E. S. Bishop); an enumeration of results derived from experience in colotomy (Mr. Jessop, of Leeds); on gastro-enterotomy (Mr. Oliver Pemberton); and the treatment of intestinal obstruction, by Dr. E. Waters and Mr. J. H. Morgan.

The special sections are abundantly well supplied with valuable material in the shape of original papers. That of Pathology will, moreover, be the scene of discussions on micro-organisms in disease, on the pathology of dropsy, on chronic bone inflammation, and on primary growths in the urinary tract. In connection with this last subject a special museum has been arranged, and the exhibition will prove an instructive and interesting one.

The total number of papers announced to be read reaches, as we have said, 235, the sections of medicine and surgery taking respectively 47 and 43. This is in addition to the particular subjects chosen for separate discussion in each section, the nature of which, and the claims they will exert on the time and attention of the meeting, may be imagined from the examples we have cited. The amount of work down for accomplishment by the Association is, indeed, prodigious ; and it is only to be hoped that as few papers as possible may have, perforce, to be "taken as read." That the outcome of the gathering will be anything but advantageous to medicine in this country is, of course, impossible ; but, besides adding to the scientific knowledge we possess, it acts even more usefully and powerfully for good by bringing together in common fellowship those followers of the profession who, but for such opportunities of mutually exchanging sympathies and ideas, might never possibly meet. In this way, as an engine of social union, the Association meeting is no less successful than as a lever for advancing the profession of medicine.

THE TUBERCLE BACILLI WAR IN GERMANY.

It is a noticeable feature of the discussion on the bacillus tuberculosus question that whilst we have abundant evidence from clinicists and general pathologists, nearly the whole of the experimental pathologists who have given us the results of their labours on the subject might be counted on the fingers of one hand. The clinicists seem almost unanimous in their utterances. Both at home and abroad we hear of Koch's bacillus being found in greater or less abundance in almost all cases of tuberculosis, and of its conspicuous absence in all non-tuberculous discharges. It has already been placed in a position of great importance, from which it will be difficult to remove it. Our own countrymen, except as clinicists, have had but little voice in the discussion. The spirit of inquiry is not dead amongst us, but the paralysing influence of repressive legislation has so overpowered it with its benumbing influence that, as far as the present inquiry is concerned, it might as well have been dead as alive. Thus it must be in regard to many questions in the future. It cannot be denied that experimental pathology has received a blow at the hands of the Government of this country that it never can recover from, so long as the insulting Cruelty to Animals Acts have their present force. In the solution of the question before us, then, we have only to rely on clinicists at home and abroad, and those experimental pathologists who have not the fortune to reside under our own advanced *régime*.

It is for the reason that most of the experimental work bearing on the question before us has been done abroad that we have been careful to give our readers the opportunity of studying the varying phases of it. We in this country, and clinicists generally, are studying the supposed diagnostic and prognostic value of Koch's bacillus, almost to the exclusion of the previous question—Is the bacillus tuberculosus a distinct species? This is the prime question on which much of its value depends. Whatever may be the diagnostic value of the bacillus, its pathological value is something totally distinct from it. The two values are not in any way dependent on each other. The *Allgemeine Weiner Medizenische Zeitung* points this out very clearly, and at the same time draws attention to the tendency there undoubtedly is when its diagnostic value is demonstrated to look upon the other as proved along with it. We have already brought forward evidence to show that the bacillus of tubercle is met with in non-tuberculous diseases, and even in the discharges of perfectly healthy individuals ; and that tuberculosis can be and has been produced artificially by inoculation with non-tuberculous substances, the inoculation being carried out in such a manner as to exclude the possibility of tuberculous matter being inoculated at the same time. We may mention here, by way of parenthesis, that some of the recent inoculations carried out by Cohnheim and others were made in the anterior chamber of the eye of rabbits and guinea-pigs, and that other observers protest against the results of such inoculations being taken as proof that indifferent substances cannot produce tubercle, inasmuch as the anterior chamber does not afford a suitable soil for the development of tubercle. It is well known that inoculation with undoubted tubercle in this locality generally fails to produce tuberculosis. Failure is the rule and success the exception. In fact, it was this very want of success with true tubercle that led experimentalists to substitute "bovine tuberculosis"—a name given prematurely since it has never been proved that "grapes" and tuberculosis are identical. Professor Spina will have as much right to call his powdered glass and cinnabar metallic tuberculosis as the author of the term bovine tuberculosis had to bestow it as he did.

But to return. In the abstract of the lecture, by Dr. C. Theodore Williams, on "The Relation of Tubercle Bacillus to Phthisis," published in these pages on June 27th, the following passage occurs :—"The sputum was examined in about 200 cases. In 23 the patients were suffering from lung diseases other than phthisis . . . In none of these did the sputum contain bacilli. In the cases of phthisis, in all save three bacilli were detected." These words are characteristic. None perhaps could be found that would in a general way better accord with the observations of most clinicists. The sputum has been examined in a large number of cases of phthisis, the bacillus of tubercle was found in almost all, but not absolutely in every one. It has been examined in about one-tenth as many cases of other diseases of the lungs, and in every case with a negative result. Why has it not been sought for more frequently and assiduously in non-tuberculous diseases? Kaberhel and Mátray sought for it 144 times in non-tuberculous diseases, and succeeded in finding it 6 times in 54 preparations. It will be remembered that in our last notice on this subject we stated that Dr. Gärtner found it necessary to allow decomposition to take place in the liquids to be examined, and that when he had taken the precaution to do this bacilli were no longer absent.

Professor Spina has not contented himself with examining tuberculous structures and sputa only, but has subjected non-tuberculous sputa and tissues to examination. He has examined well-marked tuberculous tissues, and has failed to discover Koch's bacillus, although he confesses that he has rarely failed to find it in tuberculous sputa. Judging from his own observations, Spina concludes that the tubercle bacillus has a certain diagnostic significance, but that too high a value has been placed upon it by Ehrlich, Balmer, and others.

◆

DISTINCTIONS TO THE PROFESSION IN IRELAND.

The strong feeling which both the profession and the general public in Ireland have evinced in reference to the conference of knighthood there while baronetcies have been granted with a liberal hand in England, has not been mitigated since we last wrote, nor could it be reasonably expected that a calm would follow upon the somewhat offensive reply of Lord Spencer to the memorial submitted to him. His Excellency "acknowledged the receipt of the memorial *from certain members* of the medical profession in Ireland. His Excellency is unable to consider that the bestowal of honours by the Crown can be made the subject of discussion between him and any public body, and therefore, while entertaining great respect for those who addressed him, he must decline to discuss with them the question which they have brought under his notice. His Excellency, however, wishes to assure them that Mr. Gladstone is fully aware of the high estimation in which the medical profession in Ireland is held, and desires to do justice to its members, and heartily shares in these feelings."

We would say, on behalf of those who presented the memorial to the Lord Lieutenant, that their intention was entirely misconceived if it was supposed that they contemplated entering on any controversy or discussion on the subject. They felt that it was already sufficiently clear that the profession in Ireland was entitled to such distinctions as were granted in recognition of equal attainments elsewhere, and it would not have accorded with their dignity to do more than assert this opinion with emphasis, and, with equal distinction, to repudiate the offer to them of inferior distinctions.

But, if the profession had seen fit to discuss the question of its own equality with the profession elsewhere, we must hold that it was entirely open to them to do so, and that the theoretic ground for withdrawing the subject from discussion because the grant of these distinctions is the prerogative of the Sovereign is mere sophistry. If Her Majesty pleased to mark her estimation of a member of her household in personal attendance, no one would cavil at the exercise of the Royal prerogative; but when the decoration is conferred as a recognition of scientific attainments or public services, and when it is conferred actually by the Government, though nominally by the Queen, the public acquires at once an indisputable right to criticise the advice given to her Majesty, and to protest against an improper exercise of the authority of the Prime Minister in this respect.

We know that when, by Her Majesty's Royal prerogative, special advancement is given to eminent members of the military profession, the exercise of that prerogative is criticised in and out of Parliament, and the right to take exception to it is fully admitted. We insist, therefore, that the Queen's advisers are not protected from their responsibility for the dispensation of medical honours, and that the Lord Lieutenant, as such adviser, might, if he desired, hear representations on the subject without any sacrifice of dignity or precedent.

The *British Medical Journal* says that "it is certainly felt in England that the distribution of honours from the Crown has been judiciously guided by its political and medical advisers," a statement which may be read to mean that Ireland was properly placed in a position of inferiority in this matter. We shall not argue with our contemporary a question which can only be decided by the weight of scientific and public opinion, but we believe we do no injustice to the physicians and surgeons of England and Scotland when we declare our conviction that they have brethren in Ireland as fully entitled to marks of public and Royal favour as any of themselves. This is, at least, the feeling in Ireland, and, as the profession are guardians of their own honour, they are at liberty to refuse, and they have, as a body, refused to be graded at the bottom of the professional scale.

The Government of the day may withhold from Ireland the distinctions which are suitable for scientific eminence, but if they do so they will act wisely to reserve for recipients who gratefully accept such dignities, the knighthood which they have kept in store for Irish medical use. As a matter of diplomacy, nothing can be less discreet than, without necessity, to administer to a numerous and not uninfluential class a deliberate insult. Her Majesty has not done this, but her advisers have, and they cannot reasonably expect anything but an angry retort will be delivered when the political influence of the profession comes to be exercised.

◆

Notes on Current Topics.

New Medical Titles.

Within the past week two of the most worthy representatives of the profession in England have received the distinction of a baronetcy in recognition of their eminent position as consultants, and in reward for their exalted services to medicine and surgery respectively. Sir Andrew Clark has long held a position which practically ensured his being, sooner or later, included among those who have attained the supremest height to which it is open for medical men to aspire in this country; and we take it that no one of our readers will hesitate to congratulate him on the acquisition of titular honour, or fail to endorse the opinion that he has abundantly won the reward he has received. By sheer force of character, combined with practical ability of high order as a consulting practitioner, Sir Andrew Clark has steadily worked his way to the front rank of living physicians; and while there has gained the respect and esteem of his brethren, not at home only, but throughout the world. He has studiously and successfully upheld the dignity of his calling; and as a teacher he has done not a little to influence the progress of medicine during the past two decades. To such a man additional honours can bring no additional stimulus to work; but the best that can be given him is a right and fitting recognition of his efforts to promote the general good.

Mr. Prescott Hewitt is likewise well deserving of the distinction which, of like kind with that conferred on Dr. Andrew Clark, has been accorded to him by Her Majesty's advisers. In the records of surgery Mr. Hewitt's place is a very honourable one, and his devotion to the art of which he is a master is not inappropriately acknowledged in the compliment now paid to him; while his personal services to the Royal Family would not naturally have been less considerably rewarded. He enjoys, however, the certainty of knowing that the surgical profession has already expressed the highest opinion of his merits by electing him to the premier office of the Royal College of England; and it may safely be said that his more recently received distinction will be no less popularly regarded as a well-merited one than was that conferred on him by those who voted him into the presidential chair of the College of Surgeons.

It would be affectation to deny that the creation of two new English baronets so soon after the rejection of knighthood by Dr. Banks is calculated to arouse a feeling of the utmost regret at what has the appearance of injustice. Nor can we hesitate to express the opinion that the claims of Irish representatives of medicine do not receive adequate recognition at the hands of the present Government. Such neglect as has been shown is universally regretted by members of the profession in England, who would most heartily rejoice to have the opportunity of congratulating their Irish brethren on the distribution of the highest attainable honours among their distinguished compatriots; and we ardently hope that such an experience may even yet be speedily extended to us, as a result of re-consideration by the Government of their late action with respect to this question. The brotherhood of medicine is sacred and of tender fibre. It may not be so roughly disturbed as must be the case should shocks like those recently delivered be frequently applied to it; and none so keenly regret, because none so surely know, the injury likely to arise from the dispensation of unequal justice in the matter of rewards as those who are directly interested in the honour paid, or the slight done, to their own immediate representatives.

The Cost of Irish Pauperism.

The following is a statement of the Parliamentary Grant for Medical and Educational purposes, and for Salaries under the "Public Health (Ireland) Act," according to the annual official return just issued:—

	Amount allowed for the Year. £	s.	d.
Medical purposes	74,925	18	8
Educational purposes ...	10,341	3	10
Total for Medical and Educational purposes ...	85,267	2	6
For Salaries under Public Health Act	14,237	8	9
	99,504	11	3

The total amount allowed under the Parliamentary Grant for Medical and Educational purposes for the year ended 25th March, 1882, namely, £85,267 2s. 6d., is £2,431 6s. 9d. more than the amount for the previous year.

The amount of Salaries under Public Health (Ireland) Act, namely, £13,237 8s. 9d., is £521 6s. 10d. more than for the previous year.

While the total expenditure of Poor Rates, for all purposes, viz., relief, medical relief, burial-grounds, registration of births, deaths, and marriages, sanitary measures, expenses under Superannuation Acts, payments under Cattle Disease Act, and under National School Teachers' Act, was, in 1881, £1,251,617, making a poundage of Is. 9¾d. on the valuation, the expenditure in 1882 for those purposes was £1,255,973 being an increase in the total expenditure of £4,356 and making a poundage of the expenditure on the valuation of 1s. 9¾d.

The current sanitary expenditure for the year was £51,345 in comparison with £48,918 in the previous year.

And the following shows in more detail, and under the usual heads a comparative statement of the expenditure for the two years ended September 29th, 1881 and 1882, respectively:—

	1881. £	1882. £
Medical Charities Expenditure.		
1. Medicines and medical appliances	29,092	25,757
2. Rent of dispensary buildings ...	8,386	8,539
3. Books, forms, stationery, printing, and advertising	1,203	1,127
4. Salaries of medical officers ...	88,819	88,668
4. Salaries of apothecaries ...	2,711	2,761
5. Fuel, porters, and incidental expenses	13,891	15,602
Expenses under Vaccination Act.		
6. Vaccination fees and other expenses:—		
Fees to medical officers ...	12,088	13,415
Other expenses..	1,054	1,159
Total	157,244	159,028

The Medico-Psychological Association.

The annual meeting of this Association was held at the Royal College of Physicians, London, on Friday, the 27th ult., under the presidency of Dr. Orange. The forenoon meeting was devoted entirely to business deliberations of a routine character, and to a discussion of the merits of the new statistical tables, which are at present on their trial, and are to be continued for another year, with the view of thoroughly proving them, ere a permanent arrangement can be determined on. The afternoon meeting was given exclusively to the delivery of the President's address, and its subsequent criticism. Dr. Orange selected for his subject Criminal Lunacy, and contributed a very able paper on a subject regarding which few men are so well qualified to speak, and on which few if any have been able to throw so much light. From the records of the past he sketched out its history from the time when its existence was recognised in science or in law; and he entered fully into the history of its official recognition in England during the present century. Passing on next to the ever-interesting topics of knowledge of the nature of the act committed, of controllable and un-controllable impulse, and of responsibility and its gradations, he discussed these with subtlety and painstaking care. The discussion which followed was interesting and very instructive, bristling with questions of practical importance, and suggestive of possible reforms in criminal lunacy law and administration. The publication of Dr. Orange's address will be looked forward to with pleasurable anticipation, and will undoubtedly prove a classic in the specialty.

Owing to the lateness of the hour, a paper by Dr. Campbell Clark, of the Glasgow District Asylum, had to be held over. This was unfortunate, seeing that the subject—"The Special Training of Asylum Attendants"—should specially be dealt with by the Medico-Psychological Association soon if the latter must lead rather than follow. It is a subject which is ripening fast, and commends itself to the public as well as the professional mind. Dr. Campbell Clark has devoted considerable attention to the subject, and it is to be hoped that the combination scheme which he proposes will soon be an accomplished fact.

The Health of Irish Workhouses.

It appears from the recent report of the Irish Local Government Board that the health of the indoor pauper population was average within the past year. A decrease of 1,592 took place in the total number admitted in sickness within the year, and a decrease of 27,783 in the number admitted who were not sick, while there was an increase of 450 in the number suffering from fever or other dangerous contagious disease.

The total number of deaths in the workhouses in the year was 11,272. In the previous year the total number of deaths was 11,247; so that there has been an increase of 25 deaths, as compared with the number last year.

Deaths by fever were 588, as against 552; by lung disease, 2,027, as against 2,317; and deaths by small-pox 76, as against 64 in last year.

The Price of Fame.

Another victim has paid the penalty of death as the result of rash striving to obtain the notoriety with which apparently impossible performances are greeted by the crowd. Captain Webb's tragic attempt to swim the rapids of Niagara has terminated in the destruction of the swimmer, who alone regarded the task he had set himself as other than a bold and foolhardy experiment. Such an ending to a brave man's life is a melancholy one, and is to be regretted on many accounts. By his frequent illustrations of the powers of endurance possessed by the human body, Captain Webb had afforded much information that is useful from a physiological point of view; and it is sad to reflect how worse than purposeless was his last experiment in natation. The effect of his unwise proceeding has already been shown in this country by a fatal accident at Preston, on Friday last, when a local swimmer undertook to emulate Webb's example by swimming a whirlpool which exists in the river Ribble. His exclamation, "I'm doing Webb," was only too completely realised; for, like his unfortunate prototype, he failed to emerge alive from the rapid, having been speedily overcome and drowned. How many more victims of the same craze will be chronicled remains to be seen. One and all prove the existence of an unwholesome and silly proclivity to senseless "deeds of daring" which is commonly found inherent in a certain class of Englishmen, and with undue frequency leads them into destruction.

A Test of the Efficiency of Compulsory Notification.

The *Lancet* of July 21, has a valuable editorial upon the experience of Leicester and Warrington of the efficiency of compulsory notification as a safeguard against the dissemination of scarlatina. These towns both acquired their notification powers in 1879, and they both possess an hospital for infectious diseases.

Eliminating small-pox, typhus, which occurs at long intervals, and also measles, and whooping cough which are seldom notified with any regularity, there remains, scarlet fever, a disease which appears to be distinctly amenable to such measures as isolation and disinfection, if only they are applied in time, and which causes in England and Wales a mortality averaging some 17,000 per annum. It is, therefore, natural that we should look to Leicester and to Warrington to see what has been effected as regards this very fatal disease.

First as to Leicester. The number of scarlet fever cases which have been heard of under the compulsory system of notification during the three years 1880-82 have been 766 in 1880, 1,023 in 1881, and 722 in 1882, and the admissions to the infectious hospital were at the rate of 30 per cent. of the cases reported in 1880, 38 per cent. in 1881, and some 60 per cent. in 1882. This result is so far satisfactory, and it proves that the facilities for securing isolation are steadily on the increase; but when we come to compare the scarlet fever epidemic which, beginning in 1879, has prevailed in Leicester during the three years 1880-82, with previous epidemics, the result is less assuring. Scarlet fever has been five times epidemic in Leicester since 1855. The first epidemic 1857-59, caused a total of 310 deaths; the second prevailed 1862-64, caused 294 deaths; the third 1870 and 1871, caused 381 deaths; the fourth commenced in 1874, continued to the end of 1877, and caused 415 deaths; whereas the last 1879 82, caused 478 deaths. The total mortality caused by each of the last three epidemics has, therefore, gone on steadily increasing, and even calculating the mortality for each group of epidemic years on the mean of the rapidly growing population, the rate gives but little assurance of good done, for it has only varied between 4·7 per cent. in the first and 3·9 per cent. in the last. That obtaining during the last two epidemics has been practically stationary, whereas the epidemics differed from each other in the fact that, in the latter of the two the compulsory system of notification was in operation, while no such facilities were available in the former. Dr. Johnston would take credit for a reduction in the rate of mortality amounting in the last epidemic, as compared with three of its predecessors, to 0·4 per cent. It is true, the late epidemic wave of scarlet fever maintained its force in the other large towns with much the same virulence and for much the same time as was the case in Leicester; but considering the fact that many of these towns have had no system of notification and no infectious hospital worthy of the name, Leicester, should, when compared with these towns, have shown very different results.

Turning to Warrington, we find that in 1863 there were 383 fatal cases of scarlet fever, that in 1869 there were 109, and that in 1878 there were 104. The disease again appeared in an epidemic form in the middle of 1880 ; all the cases were recorded under the compulsory powers procured in the previous year, and the admirable infectious hospital was largely used for the purposes of isolation. But since June, 1880, not a month has passed without scarlet fever cases being notified and scarlet fever patients being removed to hospital; and, so far as can be judged from the last report of the medical officer of health, the disease still continues its course, all but, if not quite, unhindered. In the latter half of 1880 some 70 cases were recorded, and over 50 were removed to hospital; in 1881, over 360 cases were recorded, and some 300 were removed to hospital; in 1882, over 300 cases were recorded, and about 200 were removed to hospital. This result is practically that which has been observed at Leicester, and unfortunately the epidemics did not show signs of having ceased at the end of 1882, up to which date the reports relate.

Thus, in so far as these two large towns are concerned, the compulsory notification of scarlet fever cases has not yet had the result that was anticipated. The annual rate of mortality, as compared with certain years of previous epidemics, has been reduced; but this appears to have been due solely to a prolongation of the epidemics; and it is, after all, no great gain to find some 300 or 400 cases of scarlet fever in one town or deaths in the other spread over four years, instead of being concentrated within one or two years.

Pauperism in Ireland.

The Irish Local Government Board in their last report notice that the number of persons receiving relief which had been increasing in each successive year since 1877, and which reached the maximum in 1881, began to decline in 1882, and that there was a decrease in the number of workhouse inmates, as well as in those on out-door relief, during that year as compared with the previous year. They now report a continued improvement in the same direction, the average daily number of workhouse inmates in the last year having been less by 2,203 than in the previous year, and the average daily number on out-door relief having diminished by 1,361.

The Germ of Yellow Fever.

A distinguished Brazilian physician, Dr. Domingos Friere, reports the discovery by himself of a specific cryptococcus in the blood of patients suffering from yellow fever, and he gives the name of Zanthogenicus to the new organism. The Philadelphia *Medical News* describes the phases of development of the germ as exhibiting minute points, and large round cells with greyish or fringed margins, and bright transparent centres. A gramme of blood charged with these organisms from a yellow-fever patient was injected into the veins of a rabbit, which died in a quarter of an hour with tetanic convulsions. Visceral congestions were found at the autopsy similar to those seen in persons dying from yellow fever, and the blood contained cryptococci like those in the inoculating material. Abundant cryptococci were also found in the blood of a guinea-pig which had been hypodermically injected with blood from the rabbit first infected, death having occurred in the former animal also, and likewise in a second guinea-pig inoculated from it. Dr. Friere regards cemeteries as perennial foci of yellow fever, for, having confined a guinea-pig in a chamber with earth taken from the grave of a man who died a year previously of the disease, the animal died after five days, and its blood was crammed with the characteristic cryptococci in various stages of development.

Dr. Banks.

It has been stated by a contemporary that, "after the honour of knighthood had been offered to, and accepted by, Mr. Porter, a like honour was offered to Dr. Banks, who has not, in view of the expression of the opinion of his colleagues in Dublin, felt it consistent with his professional duty to accept the gracious mark of favour offered to him." From this statement it might be inferred that the offer of knighthood to Dr. Banks was an *arrière pensée* of her Majesty's advisers, and that the distinction (?) might have been accepted only for the strong feeling against its acceptance shown by the profession in Ireland. Both of these inferences, we think it right to say, would be totally incorrect. The offers of knighthood to Dr. Banks and Mr. Porter were, we believe, contemporaneous, although by an error the first letter communicating the offer did not reach Dr. Banks until a few days after its date; and we are aware that in the interval, and before the profession had been informed on the matter, or had expressed any feeling thereon, Dr. Banks had, without hesitation, declined the offer.

It was last week contemplated by the profession in Dublin to entertain Dr. Banks publicly at dinner, in recognition of the regard for the dignity of the profession evinced by his refusal of the proffered title; but—as he emphatically deprecated such a demonstration—the idea was abandoned. Nevertheless, the profession in Ireland feels strongly that the President of the Irish Academy, and Physician to Her Majesty, showed a due regard for his position, and for the status of medicine in Ireland, in declining the decoration placed at his disposal by the Queen's advisers; and the profession in Ireland is grateful to him for making it clearly understood that they emphatically object to being relegated to comparative inferiority as compared with their brethren in other parts of the kingdom.

Whatever contemptuous estimate may be formed by Her Majesty's advisers of the social and scientific rank of Irish physicians and surgeons, they have at least sufficient *amour propre* to refuse the "back seat" kindly proffered for their acceptance.

Hospital Administration.

At the recent conference on Hospital Administration a committee was appointed to take into full consideration the whole subject then brought under review, and to take such steps as might seem necessary to secure the reforms deemed to be necessary in connection with improvement in the methods of carrying on the management of our great hospital charities. The first meeting of this committee was held on Monday last, at the offices, 1 Adam Street, Adelphi, London. It consists of the Earl of Cork and Orrery, Viscount Powerscourt, Sir Thomas Fowell, Dr. H. W. Acland, Dr. J. S. Bristowe, Mr. H. C. Burdett, Dr. Farquharson, Canon Erskine, Mr. S. L. Gregson, Mr. Timothy Holmes, Mr. J. T. Gurney, Mr. G. B. Lloyd, Mr. F. S. Powell, and Mr. Joseph White.

The Irish Poor-law Medical System.

The following statistics of the relative number of "black," or dispensary tickets, and "red," or visiting tickets issued during the past year indicate a remarkable decrease in the prevalence of pauper medical relief in Ireland.

In Ulster there has been a decrease of 4,626 cases prescribed for at the dispensaries, and a decrease of 1,494 of those attended at their own houses.

In Munster there has been a decrease of 6,914 cases prescribed for at the dispensaries, and of 3,607 of those attended at their own houses.

In Leinster there has been a decrease of 1,143 cases prescribed for at the dispensaries, and an increase of 3,488 of those attended at their own houses.

In Connaught there has been a decrease of 1,955 cases prescribed for at the dispensaries, and a decrease of 1,706 of those attended at their own houses.

The last three columns in the table show a decrease of 17,357 cases for all Ireland, including both classes, as compared with previous year.

In 1882 there had been a net decrease of 76,918, in the number of cases throughout Ireland, as compared with the previous year, and it is satisfactory to observe that there was a further decrease in the cases for the year 1882.

The Amsterdam International Medical Congress.

The Congress which met two years ago in London with so much *éclat* meets this year at Amsterdam on the 4th of September, and as several distinguished physicians of Great Britain, France, Belgium, Germany, and America have promised to attend, the meeting, it is expected, will be very successful, though such great things are scarcely expected as at the previous Congress in London. Amongst the papers and addresses promised by our own countrymen are several on the subjects of cholera and other important diseases, and on the remedies used by the natives of tropical countries against dangerous epidemics, by Sir Joseph Fayrer, M.D., Dr. J. Ewart, Dr. F. de Chaumont, Dr. E. Waring, Dr. J. B. Scriven, Dr. Norman Chevers, and one by Dr. Dyce Duckworth, "On the Education of Physicians for the Colonies."

Medical Aid for Egypt.

An application having been made to the British Government for medical men to be sent to Egypt, the following left last week for the seat of the outbreak:—Dr. Theodore Acland, St. Thomas's; Dr. Gulliver, St. Thomas's; Mr. H. Crookshank and Dr. McNalty, of the Indian Medical Service; Mr. James Cantlie, of Charing Cross Hospital; and with him the following members of the same hospital:—Messrs. Taylor, Houman, and Wigborn; and Messrs. Thrapp, Parker, Wilkins, and Leslie. On arrival in Egypt these gentlemen will at once report themselves to Surgeon-General Hunter, who has reached his destination, and is engaged in superintending the work of the hospital staff. They will be subject to his direction, and we may be permitted to hope, with some justice, that under their energetic action a speedy improvement will be manifested in the miserable arrangements for dealing with the cholera-stricken inhabitants already commented on in accounts sent home from Egypt. Hearty good wishes will accompany all those who have gone to lend assistance in this emergency, from those who have been left behind; and an earnest hope will be expressed that every member of the little band may return unreduced in health and strength after satisfactory conclusion of their labours abroad.

The Royal Medical Benevolent Fund Society of Ireland.

The Annual Report of the Society shows that during the past year the sum of £1,149 has been distributed; leaving a balance of £290 in the treasurer's hands, to meet the necessary working expenses.

Of the sum distributed, £185 is to medical men; £839 to widows; and £125 to orphans.

Ad interim applications were made in nineteen cases. To twelve of the applicants under this heading grants were made ranging in amount from £5 to £20. Two cases, not being urgent, were postponed to the annual distribution; and in three instances the application was refused as ineligible.

One hundred and twelve applications for relief have been received during the past year. Of these 8 were from medical men, of whom 5 were new; 91 from the widows of medical men, of whom 11 were new; and 13 from orphans, of whom 4 were new.

Meeting of the Executive Committee of the General Medical Council.

The Executive Committee of the General Medical Council held a meeting on July 4th, at which they received a legal opinion from Mr. Muir Mackenzie, to the effect that the giving of a false death certificate is punishable as a misdemeanour. This decision has a serious bearing upon the unqualified assistant system, which was brought under notice of the Council so ably by Dr. King Chambers at its last meeting. It would seem that the unqualified assistant who signs a death certificate in the name of his employer, and the employer who signs a certificate without having attended the deceased, are alike liable to be locked up and to take their punishment as misdemeanants. Such being the law, we only want some one to enforce it, and we presume that the Registrar-General is responsible to bring offences of this sort under the notice of the Crown Prosecutor, and it would be the duty of that officer—if, indeed, he does anything but draw salary—to institute a prosecution.

The Executive Committee also decided to address a "circular note"—in the manner of European sovereigns—to licensing bodies to ask them what measures—if any—they take to prevent personation at their preliminary examinations. We imagine the answer will, in all cases, be *nil*, and the Medical Council will then be called upon to provide a remedy. The task will be extremely difficult, but it must be overcome, because the feeling is daily growing that personation is much more frequent than has hitherto been suspected.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

Combe and Gilchrist Lectures in Scotland.—The courses of these lectures, which have been arranged for the ensuing winter and spring, are as follows:—The Combe lectures on "Physiology and Health" will be delivered, as usual, by Dr. Andrew Wilson, in Burntisland, Dalkeith, Airdrie, Alloa, and Leith. We understand that by special arrangement a course of lectures, similar to those delivered under the auspices of the Combe Trust, will be given by Dr. Wilson in Paisley, Mr. James Coats, jun., having arranged for the delivery of this latter course. In Perth arrangements have also been made for the delivery, by Dr. Wilson, of a special course of lectures on "Health." The operations of the Gilchrist Trust in Scotland are this winter to be carried out in Galashiels, Hawick, Peebles, Selkirk, and Jedburgh. Mr. W. Lant Carpenter delivers a course of fifteen lectures in December on "Electricity and it Modern Applications," each town being favoured with a weekly lecture for three successive weeks. In January, 1884, Dr. Wilson delivers in the same towns his course, similar in length to that of Mr. Carpenter, on "The Beginnings of Life." It is gratifying to be able to chronicle the operations of these Trusts in in supplying at a nominal cost means of scientific instruction in our centres during the winter months.

Fever Epidemic at Kilbarchan.—For some time back fever has been prevalent in the village of Kilbarchan, which, from its position, might materially be expected to be in a great measure free from disease. The fever seems to have been most prevalent in these parts of the village where the streets are narrowest and the buildings most compact. Several cases have been reported in High Barholm. It is said that the village has not been entirely free of fever for the past six months.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 21st ult., were at the rate of 25 per 1,000 per annum, against 24 in the preceding week, and 22 and 23 respectively in the corresponding periods of 1882 and 1881.

Edinburgh.—Health of the City.—The mortality in Edinburgh for the week ending with Saturday, the 21st ult., was 81, and the death-rate 18 per 1,000. There were 12 deaths under 1 year and 23 above 60, of which 6 were above 80, and 1, 92. Diseases of the chest accounted for 25 deaths, and zymotic causes for 10, of which 3 were due to fever, 2 to scarlatina, and 2 to measles, the intimations of these diseases for the week being 18, 23, and 68 respectively.

The Registrar-General's Report.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, July 21st, states that the death-rate was 21·3 per 1,000 of estimated population. This rate is 0·4 below that for the corresponding week of last year, but 1·8 above that for the previous week of the present year. The lowest mortality was recorded in Perth—viz., 11·9 per 1,000; and the highest in Paisley—viz., 29·9 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·3 per 1,000, or 0·7 above the rate for the previous week. Measles, whooping-cough, and diarrhœa continue to be the most fatal miasmatic diseases. Acute diseases of the chest caused 69 deaths, or 12 less than in the previous week. The mean temperature was 53 6, being 5·3 below that of the week immediately preceding, and 4·8 below that of the corresponding week of 1882.

Cholera Precautions at Leith.—Precautionary measures have been taken at Leith in case any cases of cholera should be brought to the port. The cholera hospital at the end of the West Pier, used as a boat-house at present by the Leith Rowing Club, can be immediately supplied with the necessary fittings to turn it into an hospital, while the cholera hospital in King Street, belonging to the Local Authority, is ready for immediate occupation if it should be required. This building was used as a cholera hospital in 1866 and 1867, when the infection was brought by seamen from the Continent, and spread so rapidly that there were at one time about 400 cases in the town. In recent years, when fever had assumed an epidemic form, and the wards of the Leith Hospital were fully occupied, it has been thrown open to receive patients.

Watt Institution.—Lectureship on Physiology.—We understand that Dr. Andrew Wilson has resigned the lectureship on physiology at this institution. The directors, in accepting the resignation, instructed the secretary to convey to Dr. Wilson their expression of deep regret on hearing that they were to lose his services. We hear that several well-qualified gentlemen are candidates for the vacant post, among whom we may mention Mr. James Hunter, F.R.C.S.E., Lecturer on Physiology at Minto House Medical School. Mr. Hunter has had considerable experience in teaching, and is a very agreeable lecturer.

Graduation at the University of Edinburgh.—This ceremony is to take place to-day (Wednesday), when Professor Dickson, the Professor of Botany, is to deliver the graduation address at the capping of the medical graduates.

Edinburgh Health Committee.—The Public Health Committee of the Edinburgh Town Council, at a meeting on the 24th ult., remitted to Bailie Clark (convener), Dr. Russell, and the medical officer, to take steps to ensure the immunity of the city from cholera, and to report to next meeting of Committee. Orders were given to enforce better sanitary arrangements in several cases of defective house construction and smoke nuisance, including the smoke nuisance at the Royal Infirmary.

Correspondence.

THE PREDISPOSING CAUSES OF CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The "Notes on the History of Epidemics of Cholera" in the last issues of your journal from the able pen of Surgeon-General Gordon are most exhaustive as to the facts of the history of the incidence of the disease, but seem to throw no light upon its causes or treatment. As to the former unless we distinctly grasp them our efforts at prevention will be futile. With regard to treatment I do not intend to say a word because I believe in the old proverb that "prevention is better than cure." Dr. Gordon's facts do not throw any light upon the apparent periodicity of the disease which reappears in England pretty regularly every seventeenth year.

When the disease was raging in the East of London in 1866 I was requested to find suitable gentlemen to take special duties in that district, and this brought me in contact with the circumstances existing in that district, and induced me to visit Dr. Norton who had charge of an extensive area near the East India Docks where the mortality was frightful. On the occasion of my visit I was strongly impressed with the idea that the districts supplied with water from the river Lea suffering most, it was in that direction we should look for the predisposing causes, and full of this notion I asked for information from my friend. He gave me no direct answer at the moment but took me out with him to a street near his house in which he had attended many very bad cases. This street ran due east and west, the backs of the houses on the one side facing due south, and on the other due north, and he said to me: "The whole of this street is supplied with Lea river water, both sides were built by the same man *upon the same plan*, and the houses are alike in every particular yet on the one side I have fresh cases every day. and on the other I have never had one." This seemed to me a very good test case because it was free from the complication which usually mislead, and it seemed possible to so exclude the various influences affecting *both* sets of houses equally so that one might see what were the influences which affected one side of the street only.

The conclusion at which I arrived was that cholera was prolific wherever the drinking water was exposed to the heat of the sun, and that as on the one side of the street *all* the cisterns were exposed to sunlight, whilst on the other they were in shade, this was the difference of condition which formed the main element in the awful result.

Talking since with officers who had the command of troops in tropical climates I have learned that where soldiers on the march drink surface water (*i.e.*, water exposed to the heat of the sun) it invariably brings on cholera, or at least that every case of cholera could be traced to drinking such surface water.

To what extent can these views be confirmed by experience? If they do not bear the inference I have drawn from them how can they be explained so as to be in harmony with other facts?

I am, yours obediently,

J. Baxter Langley.

50 Lincoln's Inn Fields, W.C.

CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your annotation founded upon a statement made in a daily paper is so eminently misleading that I trust you will allow me to state distinctly that *not one woman* has ever been discharged from any hospital whatever, in consequence of Mr. Stansfeld's motion. All allegations to the contrary are simply untrue, have been officially denied in the House of Commons, and have been withdrawn by their originators. As to the periodical examinations, they constitute a very uncertain test as to the amount of disease among the women examined. Dr. Despres, who was for 30 years chief surgeon to the great Lourcine Hospital in Paris, says: "It is evident that nothing whatever has been done to check the transmission of syphilis; the women inscribed form but the tenth part of the women who transmit syphilis; and women are registered as *perfectly healthy* who are also in a condition to communicate the disease." The tables furnished by Pucte and Fournier reproduced in Lancereaux's work show that out of 873 men who contracted true syphilis in Paris, 625 owed their misfortunes to public prostitutes who, if such regulations had been worth a rush, would have been free from disease; and Mr. Wolferston, late house surgeon to the Royal Albert Hospital, Devonport, in his evidence before the Royal Commission showed that 600 women who, in the opinion of the four honorary surgeons (after repeated examinations) were entirely free from disease had been imprisoned in that hospital on the ground that they were diseased. Exactly the same thing occurred when the Acts were re-enacted in Bombay. The hospitals were crammed with women who absolutely had nothing the matter with them. In fact, the matter is one of doubtful medical opinion. One surgeon would report a number diseased, who, in the opinion of another surgeon, would be free from disease. Women, with very rare exceptions, sometime or other suffer from discharges, and no man living can say whether such discharge would communicate syphilis, would communicate gonorrhœa, or whether it would prove absolutely innocuous. It is an error to suppose that a woman who communicates syphilis suffers from sores herself.

In 2,000 cases, Dr. Morgan, of Dublin, only succeeded on most careful scrutiny, in discovering chancre in the female, *twenty times*. Women, also, who have once had syphilis, become protected from future attacks, they continue, nevertheless, to associate with the same class of men as the one who originally infected them, and then men infect each other through the medium of her person, although she does not present the slightest trace of disease. In short, Sir, the Contagious Diseases Act is a farce, a hygienic imposture, and an insult to the common sense of any man who has real knowledge on the subject. True syphilis, the only disease of any consequence, has increased under the operation of this silly law. Before it was enacted this disease fell off from 1879 to 1866, from 35·86 to 24·77 per 1,000 men in the army. After it was enacted the disease rose from 1866 to 1881 from 24·77 to 30·5 per 1,000. In the navy it rose from 15·7 per 1,000 men to 17·83 per 1,000 men, and a similar result has followed whenever the system has been tried.

I am, Sir, yours &c.,

Charles Bell Taylor, M.D., F.R.C.S.E.

THERAPEUTIC MEMORANDUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It has struck me forcibly for some time that a great mistake is made in the administration of tonics with which strychnine is combined, notably that very valuable therapeutic agent Fellowes' syrup. We administer the lactophosphates of calcium with great advantage, as they are well calculated to be steadfast nutrient tonics. In cases of flagging nervous power the combination of strychnine is useful for a time; and when the failure of power is merely from inertia, it may be continued with advantage for a lengthened period; but when the failure is that of nervous exhaustion, I maintain that its use is only that of the spur to the wearied horse, and in such cases the simple syrup of lacto-phosphate of calcium, such as Dusart's, or if iron be desirable, Parish's, will prove more permanently useful. I have met many cases of incipient phthisis and other dyscrasias where the patients have complained, after taking Fellowes' syrup for a week with advantage, that they have relapsed into languor, and felt a distaste to the medicine. I have never heard such a complaint of the simple syrup. It is no answer to say I have known cases where it has been used with great success and no such complaint made. The *rationale* of my objection is simple; and if the principle be established, as I feel certain it will be under more extended observation, sound practice will follow. Strychnine does not make nerve power, it calls it into action, and in this way tends to wear it out. In like manner I have used strychnine advantageously for a short time in chorea, but it soon fails to do good, and a change then to arsenic or zinc will hasten the cure.

ESPRIT DE CORPS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A letter under the above heading having appeared in your issue of July 18th, and having been also published in the local papers here, you will, I trust, permit me space in your valuable journal for my reply to that production, which I in self defence was compelled to publish.

"A letter, written by James Mullany, surgeon, &c.," which appeared in your contemporary's issue of the 25th inst., has been brought under my notice. In this letter I am distinctly accused by Dr. Mullany of applying for a Government office at a remuneration at which, he says, he declined to act. It is my duty to give this statement an unqualified denial. The simple fact is, that I in no way applied, but was offered the appointment of surgeon and agent at the usual Admiralty terms of 2s. 6d. per visit and mileage. This I declined. I was then desired to state on what terms I would accept the appointment. My terms were accepted; and, I am happy to say, are not only entirely satisfactory, to me, but also very considerably higher than those at which Dr. Mullany says he declined to act."

I may further state, that my accepting the appointment in no way interfered with Dr. Mullany, he having been ordered by the Admiralty to resign his appointment. In conclusion, I would say, adopting Dr. Mullany's own words, "what a falling off, &c.," when one member of the medical profession rushes into print, with hasty and unqualified statements against another, simply to gratify his own private malevolence. I may add that the expression "parvenu," which Dr. Mullany has thought fit to adopt, I presume "for the honour of our noble profession," will be treated by gentlemen of that profession only with the silent contempt which it so manifestly deserves.

Faithfully yours,

Ballina. G. A. O'Connor, L.R.C.P. and S. Ed.

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

The following official letter has been sent us for publication:—

Sir,—Reminding you that the 8th International Medical Congress (according to the notice published some months ago in the *Medical Press*, will be held in Copenhagen from the 10th to the 16th of August, 1884, we have the honour of communicating to you that the General Organising Committee, formed for the preparatory work, is composed of the following members, living either in or near Copenhagen: President, Professor Dr. P. L. Panum; Secretary-General, Professor C. Lange; Secretaries, Dr. O. Bloch, Dr. C. J. Salomonsen, and Surg.-Genl. Joh. Möller; Honorary Treasurer, Professor Dr. E. Hansen Grut.

The following are the Presidents of the various sections—Anatomy: Professor Chievitz. Physiology: Professor Dr. P. L. Panum. General Pathology and Pathological Anatomy: Professor Dr. C. Reisz. Medicine: Professor Dr. F. Trier. Surgery: Professor Dr. Holmer. Hygiene and State Medicine: Dr. E. Hornemann. Military Surgery and Medicine: Director-General of the Medical Department of the Army Salomon. Mental and Nervous Diseases: Professor Dr. Steenberg. Obstetric Medicine and Surgery, Gynæcology: Professor Dr. Stadfeldt and Professor Dr. Howitz. Diseases of Children: Professor Dr. Hirschsprung Ophthalmology: Professor Dr. E. Hansen Grut. Diseases of the Skin and Syphilis: Professor Dr. Haslund. Diseases of the Ear: Dr. W. Meyer. Diseases of the Throat: Dr. W. Meyer.

The special committees formed for the aforesaid sections have, when they found it useful, completed their number by members living outside Copenhagen, partly in Denmark, partly in the other Scandinavian countries.

In order that the meeting of so many distinguished medical men, whom we hope to see on this occasion, may be as advantageous as possible, the Organising Committee, following the example of the later Congresses, will communicate with distinguished men of different branches and of different countries, in order to prepare a programme. This programme, as well as the rules, will be forwarded to those of our colleagues whom we suppose to take an interest in the work of the Congress, and who might be inclined to participate in it.

In order that the programme may be ready as soon as possible, we should be pleased if communications, referring to the work of the Congress, were sent to the undersigned Secretary-General before the 1st of October next, so that it may be possible for us to have regard to them in arranging the definite programme.

The programme and rules will be forwarded as soon as possible to everyone qualified to participate in the Congress who within the limited time has announced to the Secretary-General his interest in the Congress, and his eventual intention of participating in it, if possible also which section he chiefly intends joining.

P. L. Panum, President.
C. Lange, Secretary-General.

Copenhagen, June, 1883.

H.R.H. the Princess Beatrice is expected to pay a visit to Aberdeen on or about the 23rd of September to open a bazaar in aid of a fund for extending the Sick Children's Hospital. It is expected that her Royal Highness will on the same occasion open the Duthie Park, which was recently presented to the city.

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. (a)

On several occasions previously it has been our lot to have to notice the proceedings of this valuable Society. No one who casts his eye over the literature of medicine of the last half century can have failed to observe the very prominent place which the study of morbid anatomy has now attained. At the beginning of the century it could scarcely be said to have existed at all in Great Britain. The work of Bailey is the only one with which we are acquainted that treated specially on the subject. This had been precẽded by the work of Morgagni, which, as it gave the symptoms during life, as well as the post-mortem appearances, must be allowed to be the greatest work extant on the subject. It is very probable that in these countries it was the work of Bailey which first started the idea of pathological societies. It was in Dublin, however, that this idea was, in the first instance, carried out, and the Dublin Pathological Society preceded by some years the London one. The originators were the late Drs. Green, R. W. Smith, and Stokes. In the volume before us, the President, Dr. Wilks, gives a short sketch of the rise of pathological societies, and states that the study of morbid anatomy in this way is of comparatively recent date. But in the sketch he does not allude at all to the foremost position taken by the Dublin School. We think this is scarcely fair, and is wanting in common courtesy. It is possible, however, Dr. Wilks was not cognisant of the fact. Since Dublin led off we need scarcely add that very many similar societies have sprung up. We must admit, however, that the London one is in extent the largest of all, having above 600 members, and, as a consequence, being able to publish yearly volumes like the one before us.

In a notice of this kind it would not be possible to give the full details of all the cases worthy of note. We shall, therefore, as we have done before, refer in the briefest way to what appears to us some of the more striking cases given.

The very first case, by W. A. Brailey, M.D., is entitled "A Remarkable Case of Chronic Hydrocephalus from Birth," and it is worthy of note that the patient lived to be 53 years of age. She was of weak mind, had some powers of memory, and was of a very violent temper. The head measured twenty-seven inches in circumference. The ventricles were largely dilated. A cyst containing two ounces of fluid lay under the cerebellum. She had never been able to walk. No. 3, by N. Moore, M.D., is a case of "Tumour of Optic Tract from a Case of Diabetes Insipidus." We notice it because we should like to have known more of the patient. Had he thirst? Is it not possible that the sugar may have disappeared? As to the kidneys being healthy, we believe no one now-a-days connects saccharine urine with these organs, and when sugar has been found it is known that, as the disease progresses, it may disappear, though the disease still goes on to a fatal issue. Just the same course is pursued when albumen has existed—we mean as dependent on organic disease.

No. 4, also by N. Moore, M.D., is a rare instance of pus being found in each ventricle of the brain of an infant five months old—an ounce and a-half in each. The ventricles were, of course, much dilated.

Diseases, &c., of Organs of Respiration.—In this class, No. 1, by R. E. Carrington, M.D., is worthy of note. It is headed "Case of a Nutshell impacted in the Larynx; Tracheotomy, Membranous Tracheitis, and Purulent Bronchitis; Collapse of Lungs." The interest in the case consists in the fact that the child had got the foreign body into the trachea without its being known, and when this caused irritation and severe dyspnœa, the symptoms were supposed to arise from diphtheria. We must say it was a very natural mistake to make. If, however, the existence of the shell had been known, it is quite possible its removal would have saved the life of the child. We must refer the reader to the fuller details of the case given in the volume. No. 7 (card specimen), by N. Moore, M.D., is an instance where an ulcer of the right bronchus opened the pulmonary artery, and so caused death. Though a cavity the size of a walnut existed in the centre of the right lung, there was very little evidence of tuberculous disease. This makes the case the more interesting. No. 8 (also a card specimen), by J. Abercrombie, M.D., is entitled "Congenital Cyst in Larynx." It was found in an infant of fourteen days old, who was unable to cry, and from its birth had difficulty of breathing. The cyst, the size of a hempseed, grew from the crico-thyroid membrane, and on the middle line.

(a) "Transactions of the Pathological Society of London." Volume the Thirty-Second. Comprising the Report of the Proceedings for the Session 1880-81. London: Smith, Elder & Co. 1881. Pp. 419.

Organs of Circulation, &c.—We observe several cases in this department of interest. We might instance No. 5, by B. Fenwick, M.D., entitled "Two Cases of Extreme Stenosis of the Tricuspid Orifice." This communication is an elaborate analysis of no less than 46 cases of the affection, in which the author establishes the fact that the state is very much more common (7 to 1) amongst females than males, and that it is always associated with stenosis of the mitral orifice, and would seem to be even connected with antecedent rheumatic fever. This essay—for it is such—will well repay perusal. No. 7, by J. McCarthy, is entitled "Rupture of the Arch of the Aorta from Injury." The patient was twelve years of age, was admitted into hospital in collapse, and lived so fourteen hours. It was said a pony had knocked her down and trodden on her chest: A small aperture was found in the posterior aspect of the descending portion of the arch of the aorta. There was no bony fracture. It is curious, but a well-ascertained fact, that ruptures of internal organs, such as the heart, lungs, liver, &c., will occur from external violence, and yet not cause any outward mark which would lead to the idea that such internal mischief had occurred. We have seen examples so injured of all the organs we have named.

No. 8, by W. Anderson, though too long for even notice here, is a case of much interest. It is entitled "Syphilitic Disease of the Cerebral Arteries." But there was much more disease than these words would imply. The case in its progress exhibited tetanic convulsions, which must be rare. Five minutes after death the temperature was 108·8.

No. 9, by F. Taylor, M.D., is a case entitled "Obstruction of the Mesenteric Artery and Vein, followed by Intestinal and Peritoneal Hæmorrhage, with rapidly fatal result." The patient was a child of five years of age, and was suddenly seized with violent pain and vomiting, and after some hours died. There was blood found both in the peritonæum and the small intestine. No blame attaches to anyone when we say this case is very obscure, nor can we throw any light on it. It does seem to us, however, to have been going on longer than the author would have us to suppose, and for the simple reason that it is stated "the mesentery was much thickened, and contained numerous rather large fleshy glands." Such a state, we take it, could not have occurred in twelve hours. The case is a regular puzzle, but not the less interesting. No. 13, by S. W. West, M.B., is an example of "Aneurism of Middle Cerebral Artery in a boy of 12, Rupturing into the Descending Cornu of the Lateral Ventricles." We notice this case as being very rare, and showing at what an early age disease of the arteries may occur. The boy had extensive disease of the mitral valve, as well as adherent pericardium.

Diseases of the Organs of Digestion.—No. 1, by J. T. Goodhart, M.D., is entitled "Perforating Ulcer of the Stomach, leading to fatal Hæmatemesis thirty hours after birth." This also is a very rare case. The ulcer one-eighth of an inch long, was at the cardiac end, and close to the great curvature. No. 3, by C. Turner, M.D., is a history of two cases of intestinal obstruction. They both occurred in boys, and, like every case of the kind, are of much interest. No. 4, by W. H. Cripps, may be described as an essay on what the author calls "Adenoid Disease of the Rectum" (Cancer). We confess we do not approve of the changes of names in disease which recent years have made. Is anything more conveyed by the term adenoid than by "cancer?" Sarcoma is another term now much used, and frequently to denote malignant disease. No benefit, it appears to us, arises from these changes. On the contrary, they seem to lead to greater confusion. If a new disease be discovered by all means let it be named according to its histology. But cancer is not new; nor does the microscope enable us to say positively what is cancer, and what is not. Some years since the cancer cell was spoken of constantly. Where is it now? Is it a large or small cell; angular or round? Take up any volume of pathological transactions, and read the reports of the microscopic examinations of malignant disease, and do we find anything definite stated? On the contrary, is not each report different from the other? And in numerous instances, after reading the report, we are left in total ignorance as to whether the diseased mass is malignant or not. This is not as it ought to be, and seems to us a point well worthy of being handled in a different aspect from what has yet been done. But though we thus speak against some of the changes of nomenclature, which have, of late years crept in, we would not blame any particular party; and still less the author of the essay which has led to our remarks. It will be read by everyone with interest and improvement, and is well illustrated by numerous engravings. In the same division of the subject we observe different cases of dysentery complicated with abscess of the liver. These are of interest, but need not detain us here, further than to say we believe the abscess is always secondary to the dysentery. We also see two or three instances of cirrhosis of the liver in young children; which add to the proof already brought forward that the affection is not always due to the use of alcohol, an opinion which some have held, but erroneously.

(To be continued.)

Literary Notes and Gossip.

We hear that the trustees of the Astley Cooper Prize Fund have awarded the triennial prize of £300 to Dr. William Alexander, of Liverpool. The subject of the essay was "The Pathology and Pathological Relations of the Disease known as Osteo-Arthritis, or Chronic Rheumatic Arthritis." The author holds the M.D. degree of the Queen's University in Ireland, of which he was Gold Medallist and Exhibitioner in 1870. He also obtained the Jacksonian Prize of the London College of Surgeons in 1881, and has written some very useful papers in the medical journals.

⁂

The second volume of Dr. Donald Macalister's excellent translation of Zeigler's Pathology is promised in October next by the publishers, Messrs. Macmillan and Co. This part, which contains the special pathology, is eagerly anticipated by students who are familiar with the section already issued in an English form.

⁂

Our quarterly contemporary *Brain* appears for July with three very beautifully executed Woodbury-type photographs, illustrating a careful and admirably drawn "Study of a Case of Epilepsy," by Chas. Mercier, M.B. The number is throughout exceptionally good.

⁂

Mr. Hutchinson's retirement from the post of senior surgeon to the London Hospital has been selected as offering an appropriate occasion for testifying the respect in which he is held throughout the profession. There ought not to be much difficulty in raising a sum of money in this connection sufficient to form a prize of value enough to excite at once general competition and the production of sterling work. Sir Andrew Clark acts as treasurer to the fund, and the number of those willing and anxious to testify their admiration of Mr. Hutchinson's great talents will doubtless lead to the collection of a very respectable amount.

⁂

The second edition of Mr. Charles Egerton Jennings' little work on "Transfusion" will be enriched by the addition of a preface, to be especially written for it by Sir Spencer Wells, who has exhibited much interest in the subject of Mr. Jennings' experiments. The apparatus which the latter has invented for the intravenous injection of saline fluid according to his method, has undergone certain small modifications, which Mr. Jennings regards as improvements, and the value of which has been tested experimentally on animals, a special licence under the Vivisection Act having been granted to Mr. Jennings for the purpose.

⁂

Messrs. Bailliere, Tindall, and Cox have most appropriately republished Dr. Hime's translation of Pettenkofer's "Cholera: How to Prevent and Resist It," the instructions given in which cannot fail to be especially valuable at the present time. The new edition contains also the new cholera regulations issued within the past few days by the Local Government Board, a general knowledge of which will prove serviceable should an unfortunate emergency arise to necessitate employment of the instructions given in them.

⁂

There seems to be too much reason for assuming that our acquaintance with cholera in this country will ere long become of a more practical character than it has yet been since the Egyptian outbreak, and in such a contingency danger will be lessened by so much as preparations have been forwarded to combat the enemy on its first appearance. The more widely spread, therefore, a knowledge of prophylaxis in regard to the disease, the greater will be the security of the people who are subject to its evil influences. Medical men especially should do their utmost to cultivate among the public an understanding of the real dangers to be apprehended, and of the measures to be taken against them.

⁂

SUCH a multiplicity of handbooks to nursing have appeared of late years that it must be extremely difficult for an author to introduce any novelty into the treatment of the subject. A word of praise is, nevertheless, due to a little work on "Home Nursing and Sick-room Appliances," by Miss Lückes, matron of the London Hospital. This, which is published, price one shilling, by Messrs. Kegan, Paul, Trench, and Co., comprises a lecture delivered for the National Health Society, and is an eminently practical and useful guide to nurses in the performance of their work. It deserves to be universally read.

⁂

MRS. LOUISA LOWE has been storming the "Bastilles of England," as she somewhat characteristically styles private asylums; the nature of the onslaught being that to which self-styled lunacy law reformers are habituated, and resulting in much cry and little wool. The gifted authoress, whose portrait prefaces her work, inducts her reader into every imaginary horror sketched by novelists twenty years ago, and really seems to be honestly convinced that private asylums are in this day amateur purgatories. "The Way In," "The Way Out," and other mysteries are described with evident belief in the reality of the pictures drawn; but, as may readily be supposed, the higher excitability of the authoress has led to such confusion as makes date of little moment. "The Bastilles," &c., is an interesting psychological study, and serves principally to show how extensive delusions may become if unwisely cherished.

⁂

MRS. LOWE is occasionally carried away by the exuberance of her sympathy with the captives she has surrounded in her imagination with every conceivable distress, and she then makes statements which, but for the reference they include to long distant periods, might be deemed worthy of inquiry being made concerning them. The eminently hysterical character of the whole work, however, certainly removes it from criticism, and stamps it as the outcome of too credulous sympathy.

⁂

MR. R. T. FREEMAN has published through Messrs. Churchill an exceedingly handy and useful little volume entitled "A Few Words upon Anæsthetics," in which he briefly but clearly sketches the history of the subject and illustrates very fully with drawings of various apparatus employed. The book is handsomely bound in half calf, and is both a pretty and valuable pocket companion.

⁂

STUDENTS of practical physiology will find a sheet of histological tables issued by Mr. H. K. Lewis very serviceable. All the principal preparations are named and printed on gummed labels.

⁂

THE monthly numbers of the "Index Medicus" reach us very regularly from America, but we are sorry to learn from its editor and publisher that it sadly lacks the necessary support to make it a success. It was started some few years since as a monthly record of all books and principal papers published in civilised countries, and any of our contributors who will take the trouble to turn to its pages will find their communications faithfully chronicled. This fact should be a sufficient inducement to all literary men to subscribe, and though we cannot say that to the busy general practitioner it would be of great value, yet no library should lay any pretensions to completeness which has not the "Index Medicus" among its books of reference.

⁂

DR. BYROM BRAMWELL, of Edinburgh, has issued a second edition of his "Guide to the Examination of the Pulse, and Use of the Sphygmograph," in which he has embodied additional pulse tracings, and a fuller description of the uses of Marey's and Dudgeon's sphygmographs. This latter instrument has now so fully established its reputation as the simplest and most reliable instrument, that Marcy's will probably be relegated to a useful and a grateful past. Dr. Bramwell's monograph will certainly act as an incentive to the study of sphygmography, and materially assist students to rightly estimate the value of pulse-readings.

⁂

As many of our readers are doubtless contemplating their annual holiday, and are somewhat uncertain or hazy in their ideas where to go and what to do, "The Tourist's Guide to the Continent," issued under the authority of the Great Eastern Railway Company, will be a useful determining agent. This little work, which may be aptly described as the Traveller's Bible on the Continent—for, if a stranger, he cannot do well without it—will give him the routes, the cost, and the time-tables through Belgium, Holland, France, Germany, Austria, Switzerland, and Italy, together with instructive narratives, legendary lore, and illustrations of notable spots for every town he may select, and all for the moderate outlay of sixpence.

⁂

So large has been the demand in America and England for Dr. Klein's work, "The Elements of Histology," which was reviewed in a recent number of this journal, that the first edition, issued about two months since, has been exhausted, and Messrs. Cassell and Co. have already in preparation the second edition.

⁂

AMONG the forthcoming works announced by Messrs. J. & A. Churchill are:—The Principles and Practice of Medicine, by Dr. Hilton Fagge. A Manual of Physiology for Junior Students, by Dr. Gerald Yeo. A Manual of Midwifery, by Dr. Galabin. Guide to the Diseases of Children, by Dr. Goodhart. Lectures on Mental Diseases, by Dr. Clouston. Syphilis, by Mr. Alfred Cooper; and Dr. Morell Mackenzie's second volume of Diseases of the Throat. Messrs. Baillière, Tindall, and Cox announce:—A fifth edition of Mr. Gant's Diseases of the Bladder, Prostate Gland, and Urethra. The Diseases and Ailments of Children, by Dr. Armand Semple. A new edition of Lowne's Physiology. A translation of Professor Dragendorff's Plant Analysis, by Mr. Greenish. A Pocket-book for Medical Officers of Health, by Dr. Hime. Diseases of the Ear, by Dr. Pomeroy. Impotence in the Male, by Dr. Hammond. Clinical Lectures on Syphilis, by Dr. Fessenden Otis; and a Manual of Insanity, by Professor Spitzka. The other publishers' lists have not yet reached us.

⁂

NEW BOOKS AND NEW EDITIONS.—The following have been received since the publication of our last list, July 11th:—Enteric Fever, by Francis H. Welch, F.R.C.S. Medical Guide to the Mineral Waters of France, by A. Vintras, M.D. The Filaria Sanguinis Hominis, by Patrick Manson, M.D. Æsthetical Sanitation, by W. White, F.S.A. Knapsack Handbook, by W. White, F.S.A. Reports of Trials for Murder by Poisoning, by G. Lathan Browne, Barrister-at-Law, and C. G. Stewart, F.C.S. The Hygiene of Armies in the Field, by Robert Rawlinson, C.B. The Book of Prescriptions, by Henry Beasley (6th edition). The Air Cure in Tubercular Consumption, by Henry MacCormac, M.D. Excision of the Knee-joint, by G. E. Fenwick, M.D. Cholera: How to Prevent and Resist It, by Dr. Max von Pettenkofer and Dr. T. Whiteside Hime (2nd edition). The Extra Pharmacopœia of Unofficial Drugs, by W. Martindale, F.C.S., and W. Wynn Westcott, M.B.

Obituary.

DR. MEASE, OF CAVAN.

IT is with regret we announce the very sudden death, from serous apoplexy, of Dr. Andrew Mease, which occurred last week, after an illness of only eight hours' duration. The deceased gentleman appeared in his usual health and spirits on Thursday at three o'clock. He had to be assisted out of the church and carried to his residence. Dr. Mease began his career in Elphin, where his skill won the confidence of Bishop Leslie, and when in 1841 that prelate was transferred to the see of Kilmore he induced Dr. Mease to accompany him to Cavan, where he very soon secured a large practice. As physician to the Fever Hospital when fever followed in the wake of the famine of 1847 and 1848, Dr. Mease was unremitting in his attention to the sufferers. The skill with which he fought the fell disease, and the self-sacrificing zeal with which he toiled early and late to succour or to relieve his perishing fellow-countrymen, until with body and mind over-taxed, he himself became a victim, have not been forgotten by those who remember that dark time of trial. After his recovery he went to Dublin, but domestic circumstances called upon him to give up the position he had there gained, and on the death of Dr. Roe, in 1858, he accepted the appointment of Surgeon to the County Cavan Infirmary, which he held up to his death.

Pass Lists.

University of London.—The following is the Pass List for the Preliminary Scientific (M.B.) Examination :—

First Division.

Ashe, Evelyn Oliver.
Ashworth, Percy.
Barlow, George.
Black, George.
Calvert, John Telfer.
Campbell, Henry Johnstone.
Chitty, John Shaw Willes.
Cuff, Herbert Edmund.
Fernau, Charles Hermann.
Jordon, Walter Ross.
Rennie, George Edward, B.A.
Roberts, John Lloyd.
Sadler, Ernest Alfred.
Sawyer, Ramon Alexander.
Smith, Thomas Wilson.
Starling, Ernest Henry.
Williams, John Price.
Williams, William Griffith.
Wood, Frank Lomax.

Second Division.

Adamson, Horatio George.
Alcock, Richard.
Andrews, Launcelot William.
Bahadhurji, KaikhosroNasarvanji
Baine, Lawrence Augustus.
Baker, Robert William.
Bannister, Marmaduke.
Barclay, Wilfred Martin.
Baxendell, Arthur.
Bays, James Thomas.
Berry, George Arthur.
Blake, James Edward Huxley.
Boyce, Rubert William.
Brindley, Albert Edward.
Brook, William Frederick.
Brownlow, George Percy.
Bryett, Lewis Thomas Frazer.
Bueno de Mesquita, Solomon.
Buist, James Joseph.
Burt, Cyril Cecil Barrow.
Carter, Robert James.
Cass, Arthur Morgan.
Chaster, George William.
Clark, Francis William.
Colman, Walter Stacy.
Cooke, Cecil Whitehall.
Cribb, Cecil Howard.
Cunningham, John.
Deanesley, Edward.
De Jong, Edward Meyer.
Duer, Charles.
Durham, Arthur Ellis.
Dyer, John Edward.
Edmonds, Henry Augustus.
Fawssett, Frank.
Gardiner, John.
Gault, Arthur Henry.
Gifford, George Taylor.
Gould, John Edwin.
Grayfoot, Blenman Buhot.
Grierson, George Frederick.
Hastings, Edwin Birchall.
Hebblethwaite, Harold.
Hensley, Philip Henry.
Holder, Sydney Ernest.
Johnson, Harold
Johnston, Charles Saint
Jones, David Thomas
Jones, Herbert Saunders W.
Kelsall, Henry Truman
Kingsford, Arthur Beresford
Leche, Arthur
Ledward, Milton Prentice
Lightbody, John Henry
Mackenzie, William Kenneth
Mair, Ludovic William Darra
Morgan, Morgan John
Moss, Enoch
Oliver, Charles Pye
Ord, William Theophilus
Padbury, George John
Parker, George Dines
Parkinson, John Porter
Posnett, Edward
Powell, Llewelyn William
Randall, Philip Nicholas
Rivers, William Halse Rivers
Rossall, Joseph Crofts
Royce, Mary
Sarjant, Frank Percy
Savery, Frank
Smith, Guy Bellingham
Smyth, Nugent Edward
Snell, Ernest Hugh
Sutherland, G. Whitefield, B.A.
Symonds, Henry
Taylor, Frederick Howard
Tidey, Stuart Alexander
Tonking, John Herbert
Tresidder, William Elliot
Tubby, Alfred Herbert
Tuckett, Edward Hamilton
Upham, Charles Hazlitt
Vaughan, Alfred Ellis
Vincent, Herbert Edmund
Ward, Ernest
Ward, Howard Percy
Whitehead, Henry Edward
Wood, Frank Stanley
Wood, John Edwin.

Royal College of Surgeons of England.—The following candidates having passed the required examination for the diploma, were admitted Members of the College on Monday, July 23rd :—

Allingham, Herbert William.
Arnold, Ernest Charles.
Bredin, Howard Albert.
Caldwell, Robert.
Cotes, C. E. Henry.
Des Vœux, Harold Antoine.
Iliewicz, Henry F.
Moline, Paul Frank.
Moore, William Hodgson.
Paget, Stephen.
Potter, Harry.
Shillingford, Frank Norton.
Southern, John Acton.
Sutton, Henry Martyn.
Topham, Albert Stocks.
Wilkinson, Robert Hall.

The following were admitted Members on Tuesday, July 24th:

Atkins, Ernest, L.S.A.
Berkeley, E. J. Gibson.
Brown, William Henry.
Evans, William Arnold.
Gostling, Thomas Preston.
Hubbard, Arthnr John.
Jennings, R., L.R.C.P.Lond.
Schofield, A. T., L.R.C.P.Lond.
Thorburn, William, L.S.A.
Walker, Joseph, L.S.A.
Whittingdale, J. F. L.

The following were admitted Members on Wednesday, July 25th :—

Aird, Thomas Wilson.
Bennett, Frederick William.
Broadbent, F. Collingham.
Cunnington, Cecil William.
Evans, Willmot Henderson.
Griswold, Gaspar, M.D.
Reynolds, Ernest Stephen.
Smith, P. W. Bassett.
Strathy, Philip John, M.B.

The following candidates having passed the required examination, received the diploma of Membership on Thursday, July 26th :—

Dudley, William, L.S.A.
Faraker, John Joseph, L.S.A.
Griffin, S. N. R. Palk, L.S.A.
Merrifield, Sydney Sargent, L.S.A.
Shone, Wm. Vernon, L.R.C.P.L.
Stevens Francis Joseph
Street, Charles Tidbury, L.S.A.
Tireman, Arthur Lumley.

The following candidates passed on Friday, July 27th :—

Brenton, William Hore, L.S.A.
D'Aguiar, J. Gomes, L.S.A.
Gunn, D. Stilwell, L.R.C.P.Lond.
Hodges, James, L.S.A.
Jago, Charles Sprague, L.S.A.
Lace, William Francis, L.S.A.
Ogle, Arthur Wesley, L.S.A.
Parkinson, William Joseph
Short, Thomas Sydney, L.S.A.
Spencer, Herbert Ritchie, L.S.A.
Wood, Neville Thorold.

Royal College of Physicians of London.—The following candidate was admitted a Fellow on July 26th :—

Otler, Wm., M.D., McGill, Montreal.

The following candidates, having passed the required examination, were admitted Members of the College on July 26th :—

Coxwell, Charles F., M.B.Camb.
Fox, Thomas Colcott, M.B.Lond.
Griffith, Walter S. A., L.R.C.P.
Jenkins, Edward J., M.B.Oxon.
Kilner, Walter John, M.B.Camb.
Krauss, Adolph, M.D.Munich.
Nias, Joseph B., M.B.Oxon.
Paget, William S., M.D.Lond.
Syers, Henry W., M.D.Camb.

The following were admitted Licentiates on Thursday, July 26th :—

Audland, William Edward
Barefoot, John Richard
Barron, Hunter Jackson
Bassett-Smith, Percy William
Beales, Thomas William Lewis
Blagg, Arthur Frederick
Cardozo, Samuel Nunez
Carlyon, Edward Tresiddy
Cleaver, William Fidler
Collins, Edward Treacher
Collins, Octavius Augustus Glasier
D'Aguiar, Joao Gomes
Dalton, Arthur John
Davies, Edward Cluneglas
Dowson, John
Edwards, Arthur Rea
Embleton, Dennis Cawood
Gandevia, Naoroji Baranji
Gardner, Thomas Frederick
Green, Charles David
Gunn, Donald Stilwell
Hodges, Herbert Chamney
Howard, Heaton Clark
Hubbard, Arthur John
Jennings, Robert
Johnston, George David
Knill, Edwin Gilmore
Lathern, John Simpson
Littlewood, John Oscroft
Llewellyn, David William Henry
Mason, Arthur Henry
Maughan, James
Payne, Frank Cobham
Pinching, Horace Henderson
Polson, James Ronald
Pomfret, Henry Waytes
Roberts, Arthur Henry
Robinson, Clement Sumner
Rogers, Frederick Arthur
Salter, Stephen Thomas
Schofield, Alfred Taylor
Shone, William Vernon
Square, James Elliot
Stroyan, Frederick
Tresidder, Harry Innis
Waldy, John
Walker, Charles Rotherham
Walker, John William
Walsh, John Henry Tull
Ward, Anthony Arthur
Williams, John Worthy
Wilson, Alexander
Withers, Oliver
Wood, Edward Archer
Wright, Gaskoin Richard Morden

Medico-Parliamentary.

HOUSE OF COMMONS.—Monday, July 30th.

THE CONTAGIOUS DISEASES ACTS.

In answer to questions by Mr. Hopwood and Mr. Maclver,

The Marquess of Hartington said the ratio of venereal disease in protected districts rose between 1877 and 1880 from 35 to 74 per thousand. The increase in the same period in the districts not protected rose from 68 to 119 per thousand. It would appear that in 1880 a serious wave of disease occurred. There was a sudden rise in the ratio of 27 per thousand in protected and 59 per thousand in fourteen large stations unprotected. By the returns for 1881, not yet published, he found the ratio in protected districts remained at 74 per thousand, while the unprotected districts underwent a further rise of seven per thousand, making in all a ratio of 126. It was to be observed that, while there had been undoubtedly a serious increase in the amount of these diseases in the protected districts, there had also been a considerable, though smaller, increase in the unprotected districts, which would seem to point to the fact that other causes as well as the suspension of compulsory examination had something to do with it. Under these circumstances, the Government proposed to wait the result of further experience before deciding upon entering on further legislation.

Lord E. Cecil asked the Secretary of State for the Home Department whether, in view of the abandonment of the

Detention in Hospitals Bill by the Government, and of the recent great increase of contagious disease, he could now state what steps the Government proposed to take in order to protect the health of our soldiers and sailors in those seaport towns where the Contagious Diseases Act was in force.

Sir W. Harcourt replied that the Home Department had very little to do with the administration of these Acts. They were carried out by the Admiralty and the War Office, and the only connection of the Home Department with the matter was that under the Acts the Metropolitan Police were one of the alternative methods of executing them. After the vote of the House he directed that the Metropolitan Police could no longer be so employed.

◆

Notices to Correspondents.

Mr. Meyrick.—You have been misled by your informant. There has been no award of the prize as yet, and the conditions you quote apply to the first competition.

Borderer.—We have uttered such frequent and decided opinions of the practice you seek to excuse, that any further repetition of our expressions must be wholly unnecessary. There can be but one reason why students should seek the privilege, and that a very unsatisfactory one.

Dr. Lewin.—Apparently intractable cases of eczema not unfrequently yield under the influence of pure rubber bandages properly applied. Due care, however, must be taken to fulfil the requirements of success by cleanliness and attention to personal hygiene throughout the treatment. If the trial has not been made it is well worth attempting.

A WARNING TO MEDICAL MEN.

To the Editor of the Medical Press and Circular.

Sir,—My attention has been called to an article in the *Medical Press* of July 4th, under the above heading, in which the writer suggests a compliment to me at the expense of the esteemed Sheriff-substitute of Dumbartonshire. The reporter of the case, discussed in your columns, entirely misunderstood the court procedure when he supposed that the Sheriff solicited the opinion of any member of his bar. The facts are that I happened to be beside the medical gentleman who was conducting his own case, and conducting it badly, and I volunteered a few suggestions to him. The Sheriff, assuming I was engaged in the case, asked at the close of the evidence what I had to say about it—a customary inquiry. This was not appealing for an opinion, but offering the litigant the benefit of an agent.

It is quite fair that the decision itself should be discussed. It is subject to the same conditions as every other judicial proceeding, but a left-handed compliment such as is offered, in the view of bringing the judge into personal disrespect, is an entirely different matter.

Yours, &c.,

Helensburgh, July, 1883. Geo. Maclachlan.

Doubtful.—Your patient has evidently got hold of some old pamphlet or paper of the notorious Dr. Churchill. His so-called cure of tuberculosis, which he presented to the Paris Academy some twenty years ago as a grand discovery, took the profession somewhat by surprise, but this soon gave way to the logic of facts, when, after full and extended trials by the leading therapeutists of the time—Dr. Quain, Dr. Cotton, Dr. Bennett, Prof. Binz, Dr. Dechambre, and others, and reported upon as not only useless, but even harmful, by reason of its excluding more apppropriate remedies, it became a nine days' wonder, and its propounder discredited. The ideas of patients, especially consumptives, are generally visionary, and sometimes annoying, and can only be met by the logic of common sense.

VACCINATION.

To the Editor of the Medical Press and Circular.

Sir,—Is the medical officer of a dispensary district entitled to the usual fee of 2s. for vaccinating at his own house a child living in his dispensary district when he receives a fee of £1 from parent for so doing?

Yours, &c.,

X. Y.

[The vaccinator is entitled to the official fee in every case without reserve, but it is, we think, a questionable practice for him to count private cases, for which he has been already paid as part of his claim against the guardians. However, it is frequently done.—Ed.]

R. L.—No one is permitted to engage in experimental studies involving resort to vivisection without first obtaining a licence under the Vivisection Act. The steps necessary to this are to be ascertained on application to the Research Defence Association, and involves a needless expenditure of time and trouble, but under existing restrictions no other plan is possible.

DISPENSARY TICKETS.

To the Editor of the Medical Press and Circular.

Sir,—I shall feel obliged by your kindly letting me know if I am bound to give medicine to patients on black tickets every day I receive them, as well as dispensary days? I thought I was only bound to give medicines on black tickets on dispensary days and during dispensary hours.

Yours, &c.,

M. S.

[You are bound to give advice and medicine at all times on black ticket, but there is an unwritten law which confines dispensary work as far as possible to dispensary hours, and we advise our correspondent, while giving immediate attention to urgent cases, to discourage romiscuous calls out of dispensary hours.—Ed.]

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopædic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.

TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's, 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 3 p.m.

WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopædic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m., and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Vacancies.

Brompton Consumption Hospital.—Resident Clinical Assistant. Applications to the Secretary before August 4th. (See Advt.)

Clifden Union, Clifden.—Dispensary Medical Officer. Salary, £90, and £10 as Sanitary Officer. Election, August 4th.

Leeds School of Medicine.—Curator. Salary, £80 per annum, with furnished apartments, &c. Applications to Dr. Churton, Park Sq., Leeds.

North Dublin Union, No. 1, West City Dispensary.—Medical Officer. Salary, £145, and fees. Election, August 7. (See Advt.)

Strabane Union, Strabane.—Dispensary Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, August 15.

Appointments.

Bryant, T., F.R.C.S. (Senior Surgeon to Guy's Hospital), a Consulting Surgeon to the Bolingbroke House Hospital.

Fenwick, E. H., F.R.C.S., Assistant Surgeon to the London Hospital.

Greene, F. W., L.R.C.S.I., M.B. Univ. Dub., Medical Officer to the Mallow Union Hospital, co. Cork.

Humphery, Mr. F. W., House Surgeon to the Royal Hants County Hospital.

Ilott, E., L.R.C.P. Lond., F.R.C.S. Eng., Medical Officer of Health for the Bromley (Kent) Urban Sanitary District.

Jones, D. M., M.B., C.M. Ed., Medical Officer for the Bishopstone District of the Wilton Union.

King, D. A., M.B. Lond., M.R.C.P., Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

Nall, S., M.B. Cantab., Demonstrator of Physiology in the Medical School of St. Mary's Hospital, London.

Ranger, W. G., M.R.C.S., Dental Surgeon to St. Thomas's Hospital.

Shearer, F., M.B., C.M. Glas., Dispensary Physician to the Paisley Infirmary.

Births.

Ducat.—July 25, at Gloucester House, 154 St. Paul's Road, Highbury the wife of Andrew D. Ducat, M.D., of a daughter.

Haig.—July 27, at Grove Park, Kent, the wife of Alex. Haig, M.B. Oxon., of a daughter.

Harrison.—July 27, at Falland Road, Clifton, the wife of A. J. Harrison, M.B. Lond., of a son.

Marriages.

Warwick—Burleigh.—July 26, at Halesworth, Percy Warwick, M.R.C.S., son of W. R. Warwick, M.D., of Hastings, to Helen, daughter of the late R. W. Burleigh, Esq., of Halesworth.

Deaths.

Hammond, July 24, at Lewisham, Kent, Henry Samuel Hammond, F.R.C.S. Eng., late of Edmonton, aged 92.

Kearney.—July 19, at his residence, Morpeth, James P. Kearney, L.R.C.S.I., aged 36.

Lucas, July 20, at Greenock, E. A. Lucas, L.R.C.S.I., L.K.Q.C.P.I., Surgeon, H.M.S. *Forester*.

M'Entee.—July 23, at the Richmond Lunatic Asylum, William C. M'Entee, late Resident Apothecary of Grand Canal Street Dispensary.

Miller, July 24, at 9 Rankeillor Street, Edinburgh, George Miller, M.D. St. And., L.R.C.S. Ed., aged 58.

Phillips.—July 23, at 27 Leinster Square, Bayswater, Richard Phillips, F.R.C.S., aged 67.

THE QUESTION OF FOOD IN OBSTETRIC AND GYNÆCOLOGICAL PRACTICE.

An Address delivered at the Opening of the Section of Obstetric Medicine, at the Annual Meeting of the British Medical Association in Liverpool, August, 1883.

By GRAILY HEWITT, M.D, F.R.C.P.,

Professor of Obstetric Medicine, University College; President of the Section.

Gentlemen,—I take advantage of this opportunity to present to you a few observations on a matter which has for some years deeply interested me, and concerning which I have arrived at conclusions which, to me at all events, appear to possess a certain value, viz., The Question of Food in Obstetric and Gynæcological Practice.

Now, it may appear unnecessary at this period of medical history, and in the present advanced state, as it is considered to be, of medical knowledge, to insist on the importance of food in maintaining a healthy activity of the vital processes. But a lengthened experience has convinced me that the public at large have no practical knowledge of this, and that the most disastrous effects result in multitudes of cases from the ignorance of simple physiological laws.

Engaged as I have been more particularly in obstetric and gynæcological practice, the non-observance of these important physiological laws in connection with the occurrence of diseases of the uterus, disturbances of the functions of the uterus and ovaries, and the diseases incidental to child-bed, has forced itself on my notice. It is pretty certain that the generalisation which applies to these classes of disease extend, or would be found to extend, to diseases of other organs of the body, for it is the merit of a true generalisation that it is of wide application.

There are certain terms in general use by the public and by the profession which are often employed in a vague, unmeaning, and indefinite manner—such as "weakness," "delicacy," &c.—whereby it is intended to designate a condition very frequently met with, but the essential nature of which is, as my experience has shown me, very imperfectly apprehended. It is well recognised that this weakness, delicacy, or what not, is very commonly observed not only in young women coming under the notice of the gynæcologist, but also in women who have arrived at adult age, and suffering from disorders in connection with pregnancy, parturition, and child-bed. My observation has in a particular degree been attracted to the presence of this condition. I have taken every opportunity in my power for analysing its nature and ascertaining its essential cause. One conclusion arrived at is, that this general weakness is supposed as an antecedent in cases coming under our notice as gynæcologists, and it may even be said that it is almost invariably present in a marked form in such cases. Another conclusion is, that the "weakness" is associated with and caused by a long-continued inadequate dietary, and that it is essentially what may be termed "chronic starvation." The rational view of the matter is, that this "weakness" is, in the very large majority of cases, preventable; that it should be regarded as the first stage of a serious possible disease; that it is mostly the result of chronic starvation; that it is curable to a greater or less degree in most cases; and that it is of the highest importance that it should be formally and carefully treated, as other diseases are, instead of being allowed to smoulder on until the constitution is thoroughly undermined, or until some ailment distinctly classified in our nosology makes its appearance.

It may be asserted that, as yet, neither the public nor the professional mind has seized the importance of preventive measures in regard to disease. It is, indeed, true that the sanitary engineer is at work in our houses; but it cannot be said, as yet, that anything like systematic attention is devoted to the maintenance of healthy and vigorous growth, and the prevention of those diseases which are ultimately so deadly in their effects in many cases; I mean what may be termed the nutritional diseases incident to the human frame.

The analogy between the growth of a plant and of the human organism is one which has been often pointed out. The various chemical changes involved in a continuance of healthy growth in the plant and in the animal, are well capable of definition. We know that the plant requires air, moisture, and a supply of nutritive material regularly, and in sufficient quantity. And we should know, for physiologists inform us of the fact, that the vital processes in the human organism require, for their continuance in a vigorous state, material supplies of a suitable kind, as well as hygienic surroundings, fresh air, and the like. Again, it is well known by good gardeners that nothing so effectually protects the plant from external injurious influences, from blight, from the attacks of parasites, from insects, and from the diseases to which plants are liable, as the maintenance of the plant in a state of active growth. Once let the growth fall off in its vigour, the plant becomes forthwith liable to fall a victim to canker, to the pestiferous invasion of insects, to deterioration, to weakness, and often to decline and death.

It is a remarkable circumstance that so little as yet seems to have been done in the investigation of the effects of an insufficient dietary, looking at it from the quantitative point of view, although the effects of complete deprivation of food are well known. Thus, in the last edition of Parkes' well known work on hygiene, it is stated that little is known on the subject of the effects of insufficiency of food; and the space devoted to the consideration of this matter is less than one page.

The valuable facts recorded by a series of careful inquiries into the changes occurring in the human body in a state of health do not seem as yet to have been applied at all extensively to the treatment or prevention of disease. It should be known that each day the human body undergoes, in a state of health, a certain degree of waste and loss; and that, experimentally, it has been found that health is maintained by daily administration of certain quantities of material in the shape of food. The obvious inference is that, when the supply is continuously below the amount of daily waste, deterioration must occur, and a state of weakness will result.

It is a curious circumstance that the physiological law and the popular impression—shall I say, in too many instances, the "medical" impression?—are found widely different. Physiology teaches the necessity for a continuous supply of a certain quantity of food. The popular impression is that some people do not require so much food as others, and consequently important quantitative diminution in the supply often escapes attention. I must confess that, not very many years ago, I shared in the popular impression. What induced me to form the opposite conclusion was that, in the first place, I was struck with the fact that in almost every case coming under my notice a state of what was termed "weakness" by the patient had been notably present; and, secondly, that on inquiry this weakness was almost always found to be associated with a notably deficient dietary. For the last six or seven years I have tested the accuracy and applicability of these generalisations by carefully inquiring into the past history of patients, mostly suffering from some uterine or ovarian disease, or some affection incidental to child-bed, and these conclusions have stood the test of this long-extended inquiry. I have to state the important conclusion that a continuous insufficiency of food, or what may be termed a "chronic starvation," more or less intense in different cases, was found to have existed almost universally. Consequently, I have naturally been led to consider chronic starvation as a most important factor in disease, certainly in those classes of cases which have come more particularly under my notice

It will be well to cite a few typical instances:—

1. A young married lady, aged 24, consulted me for a severe retroflexion of the uterus, which appeared to have set in shortly after her first labour, some months previously. She underwent treatment for this affection; and, in course of it, one day her mother came with her, and inquired of me why it was that her daughter had become liable to this affection. I replied that, in all probability, it was due to a previous condition of weakness, and insufficiency of meat as an article of food. "Yes," said the patient, "that is very likely true; for when I married, and could please myself, being very fond of sweets, I took little ordinary food during the first year, but lived chiefly on sweets, and ate little or no meat at all."

2. A young lady, aged 18, suffered much from menorrhagia, and her condition became finally one of complete inability for exertion. It was ascertained that this patient had lived as regularly as regards her diet, but that her diet consisted principally of bread and puddings; and, having a marked aversion to meat, she had taken very little for two or three years previously; and it is the fact that I was afterwards consulted by two of her sisters presenting uterine symptoms, and with a corresponding history as regards the previous dietary.

3. Again, a young lady of very active habits, but who hardly ever took meat, became very ill after an unusual exertion, was affected with severe sickness, which went on unchecked for nearly a year, and was finally so ill that her life was despaired of. Here, the previous dietetic deficiency was most marked. The patient was finally completely cured, the sickness being found to be a reflex symptom dependent on an uterine displacement.

These cases might be multipled *ad infinitum*.

I have been much interested in observing, also, the effects of previous insufficiency of food in apparently predisposing patients to attacks of puerperal septicæmia. In the cases of this disease which I have seen in consultation, I hardly recollect having seen a case where the patient so affected had, during the pregnancy, lived fairly well; and the worst cases have been those in which the patients fed badly and insufficiently during the pregnancy, and had been fed on a gruel diet after the labour was over. In cases where severe sickness during the early part of the pregnancy prevents the proper nutrition of the patient, the system is liable to become much impoverished, and an insufficient dietary may be, and often is, the preliminary to a dangerous childbed.

With very few exceptions—and those exceptions only tending to prove the rule—it is, I hold, impossible to find patients suffering from chronic uterine disease who have not undergone at some former period what may be termed a starvation process, and careful inquiry generally elicits the fact that the quantitative deficiency in the diet extended over a considerable period. In many cases the patients are found to be still under the influence of a deficiency in this direction, and to be "eating," as the expression is, "next to nothing."

The period of life during which quantitative deficiencies in the dietary are most common is the two or three years immediately following the arrival of puberty. The girl is at school probably; her appetite is bad, or the food is not palatable, or is deficient in important particulars, or, as I have found in some cases, she eats little in order to keep thin; the strength fails, the appetite diminishes, and a habit of taking little is formed—particularly little animal food is taken. Three or four years of the most critical stages of life are thus passed—a time at which the body should be growing fast, and to maintain this growth in adequate vigour large supplies of nutritious material are required, instead of which the supply is far below the normal standard. The result is a general impairment of vigour and of vital action. On the generative organs the effect is, as I have observed in numbers of cases, most decidedly injurious; and the effect in most instances of this kind—that the tissues of the uterus lose their normal, firm, healthy consistence. The further result is that the pelvic organs as a whole, but particularly the uterus, undergo a subsidence in the pelvis; the uterus becomes liable to change of shape, and other alterations, more or less marked, in different cases. Slight exertions, slight accidents, or even moderate exercise are, under these circumstances, liable to act most prejudicially on the softened and weakened contents of the pelvis. This is a faithful description of what I have observed to occur in very many cases. I refrain from pursuing the further history of patients so affected as not falling within the scope of these remarks.

It is generally admitted by authorities on the subject of diet that nitrogen is the most essential of all foods, and that a certain amount—about three hundred grains—should be taken daily. In cases of chronic insufficiency of food, it appears that the diminution in quantity of food most frequently affects the nitrogen. Meat is the article of diet which, as a rule, is the source of the greater part of the needed amount of nitrogen, for, in England at all events, meat is the popular article of food; and, in cases of chronic starvation, we mostly find that the quantity of meat taken is exceedingly small. "Never a meat-eater," "Do not like meat," "Have got out of the habit of taking meat"—such are common replies made to interrogations of patients under these circumstances.

No doubt meat can be replaced dietetically by other foods containing nitrogen in sufficient quantity; but practically, owing to the habits of families, good substitutes for meat are not easy to find. The weakly one of the family is too often allowed to take her own course, and, if she does not take meat, often gets nothing sufficiently nitrogenous to answer the same purpose. Of all the nitrogenous foods, meat is admitted by all authorities to be the most easily digested, most easily assimilable, and most rapid in its nutritive action. Milk is, of course, a most valuable alternative food; but, in these cases of absence of sufficient meat, we do not find it has ever been taken in any quantity as to make up for the deficiency; and the quantity of bread consumed, even supposing it to be pure and of good quality, is in such cases entirely inadequate to supply the required quantity of nitrogen. I need not allude to the effect of deficiency in the other constituents of the diet. It is sufficient for my present purpose to show that the nitrogenous elements, while they are of all the most important, are those which are markedly absent in the cases now under consideration.

There are few observations bearing on the subject now under discussion which can be quoted from published works. Professor Voit (*Untersuchung der Kost*, Munich, 1877), mentions an interesting fact. In a public institution, a home for girls, on which, he reports, the diet included an average quantity of 170 grains of nitrogen only, the girls appeared healthy, but their muscles were found to be weak, and menstruation was found to be delayed in many cases until the sixteenth or seventeenth year.

Parkes states that when the nitrogen is reduced to from 70 to 100 grains daily, the body gradually lessens in activity, and passes into a more or less adnyamic condition, which predisposes to the attacks of all the specific diseases, especially malarious affections, typhus, and pneumonia, &c.

It must be assumed from what is known that if the minimum quantity of nitrogen—which, for the sake of argument, we may put as low as 250 grains in the case of a young woman—be not given, a condition of weakness will soon be induced, and with greater or less rapidity, according as the quantity of nitrogen falls much or little below this 250 grains *per diem*. Thus it is easy to understand why in a year or two, with an average daily consumption of only 100 grains of nitrogen, for instance, important modifications of the nutritive processes are effected whereby there is produced a direct predisposition to disease.

It is now some sixteen years ago since I first publicly discoursed on the importance of nutrition in the treatment of disease. I have made it the basis of my practice for some years past, and four years ago I described the condition to which I have now again referred as "chronic starvation." In the United States Dr. Weir Mitchell has employed a system of rapid feeding, assisted by massage and electricity, for the cure of weakly, nervous sufferers—a system which has been found most successful, and Dr. Playfair has done good service in introducing Dr. Weir Mitchell's method into this country. The method in question is essentially a rapidly acting means of introducing nutritive material into the system, and it is dependent for its success on the fact that the principle of the curative influence and action of food is adequately recognised.

It is probable that it will be found on further investigation that particular deficiencies in the dietary result in deterioration of particular tissues of the body. The field for inquiry in this direction appears to be a large one. Deficiency in the quantity of meat taken certainly, according to my experience, appears to have an enormous influence in predisposing to uterine ailments, but no doubt, other organs of the body also suffer from deficiency in this article of diet. And I have abundant evidence that it plays a very prominent part in predisposing to the serious wasting diseases so often fatal in this country. I refrain from dilating further on this particular point, because such discussion would in this place be inappropriate.

The conclusion which is obviously suggested by the foregoing considerations is the necessity for a greater attention to the question of diet, in the bringing up of families, than appears at present to be given to it. We all know that health and a good appetite usually go together. But it seems to be too frequently the case that, when the appetite is absent, such absence is taken as a matter of course, and receives no notice. It results from what has been stated, that absence of appetite may lead to most serious results. It is not immediately dangerous, but it is the first step possibly in the downward course. A continuously bad appetite constitutes a grave condition, and should be seriously regarded.

If it be a rigorously proved fact that the human body is dependent for its existence in a state of vigour on an adequate and regular supply of food, it behoves us to take all possible opportunities of enforcing this principle, and in making it known as a great and universally applicable measure and precaution in the prevention of disease.

THE FRENCH EXPERIMENT FOR THE PREVENTION OF SYPHILIS.

Report of M. Fiaux to the Municipal Council of Paris.

By C. R. DRYSDALE, M.D., M.R.C.P. Lond., F.R.C.S.,
Senior Physician to the Metropolitan Free Hospital.

I have just received from Paris an interesting document presented to the *Conseil Municipal* of Paris in 1883 concerning the great Parisian experiment for the prevention of syphilis, which it seems to me is worth the attention of hygienists in this country.

It seems that in 1845 Paris contained 1,050,000 inhabitants, and at that date there were 3,966 women inscribed as prostitutes by the police; whereas, in 1880, when Paris had 2,200,000 inhabitants, there were only 3,582 prostitutes on the books of the police, who were examined for the purpose of preventing disease. M. Lecour, one of the *employés* at the prefecture of police in Paris, with whom I had a conversation in 1867, when the International Congress met there, puts down the number of prostitutes in Paris at 30,000, whilst an able writer, M. Max Ducamp, thinks there are nearer 100,000 women in Paris who might merit the name, an opinion shared, as far as I can remember, by Dr. Lefort, when I spoke with him on the question many years ago in Paris. In 1843, it appears by the report, Paris contained 235 public brothels, with 1,450 inmates, whilst in 1880 there were but 133 such houses, with 1,041 inmates. In 1855, again, there were 611 women inscribed on the books of the police, and 1,323 arrests of so-called "insoumises" were made. In 1880, there were only 354 inscriptions, and no less than 3,544 arrests of the insubordinates. So that, in short, there has been a diminution in the number of prostitutes inscribed, a diminution in the number of tolerated houses, and in the number of new inscriptions annually of recent years in Paris.

According to M. Lecour, there were in 1855, 1,852 inmates of these houses, and of these no less than 805 were suffering from contagious diseases; whilst of the remaining 2,407 of the inscribed women only 137 were found to be diseased. In 1880, again, there were 1,041 of the inmates of brothels, of whom 205 were found to be diseased, while of the 2,313 not in houses, only 102 were found to be suffering from contagious diseases.

Dr. Mireur, of Marseilles, in a well-known work of his, says, p. 363, "Of 100 cases of confirmed syphilis observed by me, half of them among my private patients, and half among those seen at my dispensary, I ascertained that 62 contagions were attributable to relations with women in these houses, and 38 to inscribed or clandestine prostitutes in the City." This seems to show that the system which was so much praised by M. Lecour of frequent examination of women in tolerated houses, is not of any great service with respect to the only point for which it exists, viz., the prevention of syphilis. The reporter, M. Fiaux, indeed, calculating that there are, on the lowest estimate, about 30,000 insubordinated prostitutes in Paris, observes that there are about 29 per cent. of the inmates of the tolerated houses diseased, as against 6 per cent. of those not in houses, and against 2·3 per cent. of those not inscribed at all.

M. Clerc mentions too, that in 1878, there were 2,300 isolated women on the police books, which number should have required 55,200 examinations by the medical staff appointed for the purpose, if each had come twice a month to the dispensary, whereas only 35,985 examinations were actually made, and it seems that each physician generally had to examine from 100 to 120 women at each visit. Sometimes as many as 400 had to be seen, a number far exceeding what any man of ordinary strength or endurance could possibly undertake to treat or examine in any serious fashion.

Syphilis is a chronic disease, with a sore or an incubation varying from 15 to 30 days, which sore lasts, perhaps, a month or six weeks, and is followed by secondary symptoms as contagious as the ulcer which precedes them. The duration of these secondary symptoms is difficult to define, in the majority of cases they appear from 60 to 120 days after the contamination, or about from 30 to 50 days after the chancre. Dr. Fournier, of Paris, whose authority on this point is considerable, estimates that such secondary accidents may relapse for as long as four years.

Hence it is, as I have always said, quite impossible to say when a syphilitic patient ceases to be contagious, for some years after the onset of the disease. This is the true reason why the prevention of syphilis is not like that of scarlet fever, measles, or small-pox, feasible by quarantine carried out for a short time. So that the police in Paris apparently withdraw from the street annually 350 women with syphilis with little effect seeing that there are always 400 or 500 of that same class in their houses affected with this chronic contagion. In my personal experience among the patients of the Rescue Society of London I have found it quite impossible to say for certain whatever be the length of time the young women stay in our hospital—and sometimes that is more than a year—that they are no longer contagious if they had syphilis on entering.

These are the reasons why I observed when visiting Parisian hospitals in 1867, at the time of the International Congress of Medicine, in that year, M. Ricord being in the chair, that it seemed to me that the Parisian system had rather increased the number of cases of syphilis, as compared with those in London, and it is for this reason that M. Fiaux recommends the voluntary admission of syphilitic patients into the general hospitals of Paris, the abolition of the prison of Saint Lazare, and urges that the hospitals of Lourcine and Midi should be turned into general hospitals. My own experience of London and Paris leads me to think that M. Fiaux may be, to a certain extent, right; and that at present, when the principles of the prevention of contagious diseases are so much better understood than they used to be, both by the profession and by a section of the public, funds would be forthcoming for the treatment of syphilitic patients in our general hospitals, which formerly were not obtainable, owing to the ignorance which was all but universal of the extent and important nature of these contagions.

◆

ON SOME RECENT ADVANCES IN THE SURGERY OF THE URINARY ORGANS.

Being the Address on Surgery Delivered before the Fifty-First Annual Meeting of the British Medical Association, *at Liverpool, on August 1st,* 1883.

By REGINALD HARRISON, F.R.C.S.,
Surgeon to the Royal Infirmary; Member of Council, Liverpool University College.

Mr. President and Gentlemen,—The selection of material for presenting to you to-day has occasioned me no little anxiety. Following immediately upon an address which will for ever render our jubilee year memorable—an address in which justice was done by the distinguished representative of surgery from Ireland to the great subject of surgical progress generally, whilst its prominent features were forcibly brought out, I may well hesitate where to tread.

In considering the position of surgery as detailed in Mr. Stokes' admirable address, the thought naturally occurs that its diffusion is as remarkable as its progress. Compare, for example, the condition of surgery prior to the existence of our Association with its present position. In the former period departures from the ordinary routine of surgical procedure were confined to a few hands, and the benefits resulting from improved methods of treatment were shared in by a very limited number. Now, no sooner, is a method of treatment or an operation proved to be efficient, than it is taken up and practised wherever scientific surgery can reach; the peer is no better off than the peasant, and the cottage hospital rivals in its successes those obtained in more palatial edifices.

So beneficently catholic is our profession that it hails with the greatest satisfaction, not only the discovery of new means of relief, but the adaptation of others to a form which permits of their more general adoption and usefulness; whilst, on the other hand, it regards with suspicion all methods of treatment which unnecessarily restrict or conceal that which was intended for the common good.

I propose to occupy the time at my disposal by a reference to some of the more recent advances and work in connection with the surgery of the urinary organs.

Commencing with the kidneys, we are at once struck with what surgery is doing for them. Until quite recently the diseases of these organs were regarded as belonging almost exclusively to the province of the physician, and probably would have remained so had preventive medicine obtained fuller development.

A more extended acquaintance with the pathology of the kidney has brought to light conditions in which the work of the physician requires to be supplemented by that of the surgeon. Pain arising from an undue mobility of the organ, tumours, deposits, hæmorrhages, and collections of fluid within it—all these morbid states are now recognised as capable of relief or cure by fixing, opening, or extirpating the abnormal or disordered organ; whilst numerous illustrations have already been afforded of the successful removal of stones from positions where they must have ultimately led to the disorganisation of the kidney in which they had become impacted.

It would be premature at present to endeavour to formulate anything like precise rules in reference to the application of the various operations on the kidney to which I have briefly referred; they are at present comparatively new to us, and we must occupy ourselves in cautiously moving in the direction they indicate, and in collecting experience rather than in drawing conclusions other than very general ones.

Amongst many valuable contributions to the literature of this subject which have appeared, I would include one by Dr. R. P. Harris, of Philadelphia, (a) which contains an analysis of one hundred cases of nephrectomy. From this, as well as other communications which have more recently been published in this country, we may draw at least three conclusions of value, so far as the operation of extirpation of the kidney is concerned. These are—

1st.—That nephrectomy has been the means of saving many lives under circumstances where no other method of treatment was likely to be of service;

2nd.—That this operation has been practised in cases where the probability of a successful termination appeared to be very remote; and

3rd.—That a method of effecting the removal of the organ different from that which was selected, or a procedure less heroic, might, in some instances, have tended to increase the chances of success.

In these directions then—in selecting cases for operation, in rejecting others as unsuitable, and in determining relatively to the case in question the best method of procedure—I take it that good work has yet to be done.

It appears to me that among the difficulties we have to contend with in the application of nephrectomy, two stand out prominently: (1) the kidney it is proposed to remove may be the only one; (2) the opposite organ may be similarly affected, though in a less degree, yet sufficient to interfere with those compensatory changes being carried out which are essential when one excretory organ has to supply a lack of service on the part of another. The literature of this subject will already be found to illustrate the class of difficulties to which I am referring.

The lesser proceedings, which include the exploration of the kidney, and the removal of calculi and of pent-up fluid, are necessarily attended with a diminished risk, and have already proved of much value.

In undertaking a new class of operations, we must bear in mind the past history of many methods of treatment, now justly regarded as successes, but which severally, had a very unpromising commencement. Look at the unsatisfactory position held by ovariotomy only within a period represented by the memory of the majority of us here present to-day. Yet the high dignity to which it has been raised in the rank of surgical operations, by the skill and enterprise of Sir Spencer Wells, Keith, and others, is now frankly and fully admitted by the whole medical world.

In the treatment of certain affections of the bladder, we shall find that much progress has been made, and that the way has recently been opened for prosecuting other important advances. These will be chiefly illustrated by the modern practice of lithotrity and the treatment of tumours and intra-cystic growths.

Till a few years since the removal of stone from the bladder by crushing had been conducted on the lines laid down by Civiale some half-century ago. Though this method of proceeding has included amongst its advocates, past and present, surgeons of eminence, it cannot be said that, as then practised, it was either gaining ground or confidence. Indeed, I think I may say there was an increasing tendency to limit its application and to substitute lithotomy in all cases but those of the simplest kind. The mortality consequent upon the retention of broken calculi within the bladder was sufficient to induce all but the most ardent admirers of lithotrity to hesitate to give it the preference over a proceeding in which, whatever might be the risks, there was at least a guarantee that the whole of the stone had been removed.

Whilst the surgical mind was thus to some extent in doubt as to the limits to which the crushing operation of stone might safely be pushed, two important communications followed rapidly upon each other. That both of them should have emanated from America merely indicates that the desire to advance the art of surgery is not limited to the old country, but is a natural outcome of advancing civilisation and humanity.

The first of these papers was by Dr. Otis, of New York, who demonstrated beyond all reasonable doubt, and in a manner which had not previously been attempted, that the male urethra was capable of safely receiving far larger instruments than were generally employed. Following upon this, and probably influencing the views of the author, came Dr. Bigelow's paper on the removal of stone from the bladder by crushing and withdrawing it at a single operation; the latter communication clearly showing that the bladder was tolerant of much more prolonged manipulation than had previously been believed.

It appears to me that the originality of Bigelow in no way detracted from the importance of the work that had previously been done in this country and elsewhere, or compromised the acumen of those who were most interested in the progress of this department of surgery.

That Bigelow's method of procedure is a great step in advance—that it has extended the limits of lithotrity and curtailed those of lithotomy—there cannot be the least doubt. But to suppose that it is capable of universal application, or ever likely to be so, is as unreasonable as to suppose that the art of surgery in no way differs from the art of administering Holloway's pills. But does the lithotrity of to-day represent the finality of its perfection? I trow not. When we consider what chemistry, electricity, and other agencies are doing—how physical force is in many directions being supplanted by other means—can we doubt that there are yet improvements in store in the methods of effecting the destruction of concretions within the body? Nay, are there not already significant indications that such improvements are nigh at hand? Is it likely that the fruit of the labours of Garrod, of William Roberts, of Ord, of Vandyke Carter, and others has been already gathered? May not a more perfect knowledge of the physical and physiological laws which regulate the productions of concretions in the human body result in enabling us not only more surely to prevent, but to destroy them?

Considering the great activity that has within recent years been shown in demonstrating the preventible nature of many diseases, and the energy that has been displayed in grappling with them, it seems remarkable that no adequate steps should have been taken to ameliorate the hygienic condition of certain parts of this country where the amount of calculous disease is excessive and the inhabitants consequently are exposed to an inordinate risk of contracting it. The admirable address by Mr. Cadge before our Association at Norwich in 1874, furnishes abundant data for the further prosecution of inquiries of this kind. I cannot help thinking that if it could be shown to be even probable that the dogs, cats, rabbits, or frogs of the aforesaid districts were inconvenienced in a like manner with their owners, the matter would long ago have been forced upon our legislature with all the exaggeration that usually characterises agitations of this kind.

Though surgery has invariably shown itself equal to the circumstances and emergencies with which it has been called to cope—though the prevalence of stone in a district has always been compensated for, as far as this is possible, by the appearance of those most competent to deal with it—these are no reasons why such conditions should be permitted to continue. Had time or occasion offered, I think it would not be difficult to prove that circumstances, either fortuitous or by design, have been found to exercise a marked influence in diminishing or increasing, in certain places, the tendency to calculous disease.

One word in reference to lithotomy before I leave the subject of stone. There is no great operation in surgery, I believe, which furnishes more successful results than this. Taking the experience of the two hospitals in this city with which I have been associated, I find there have been within my recollection 102 cases of lithotomy in persons of all ages, but chiefly in children, and operated on either by my colleagues or by myself. In only five of these cases could I ascertain that a fatal result followed. My late esteemed friend, and our former associate, Mr. Southam, speaking of his own experience of lithotomy at Manchester, informed me that he had operated 120 times, and could only recall one death. In the great majority of the Liverpool cases the stones were not exceedingly large, and I have no doubt that many of them might have been removed by lithotrity. I question, however, whether the small mortality these figures indicate would thereby have been still further diminished, even if the calculation were made on a basis corresponding with the most successful statistics in lithotrity that have hitherto been obtained.

(a) *American Journal of the Medical Sciences*, July, 1882.

Passing to tumours of the bladder, it is not surprising, seeing what has been done for tumours of the ovaries, uterus, and intestines, by Sir Spencer Wells, Keith, Lawson Tait, Treves, and others, that growths occupying the interior of the bladder should have received special attention. Though the literature relating to this subject has been of a somewhat fragmentary character, such compilations as Stein's recent work—"A Study of Tumours of the Bladder"—conclusively show that some gratifying results have already been attained in both sexes. The great distress connected with this class of growths, the uncertainty as to the precise nature of the affection in the first instance, and subsequently the kind of symptoms that accompany it, have naturally suggested the employment of means having for their object their removal by operation.

Sir Henry Thompson has done good service in giving prominence to the employment of digital exploration of the bladder, and in furnishing illustrations of the great advantage that this proceeding is capable of affording in suitable cases.

From a consideration of some of the extremely valuable records which have been published by various surgeons, where the bladder has been opened for the removal of tumours, it appears to me that it might have been better had the operative proceeding terminated with the detection and exploration of the growth by the finger. The chief dangers which experience has shown to be liable to attend the performance of this class of operations are :—

1. The chance of rupturing a bladder the coats of which have been rendered less resisting than natural.
2. The provocation of a hæmorrhage which it has been found difficult to control.
3. An incomplete removal of the growth.

On the other hand, an examination of many tumours of this kind, of which villous growths or tufts furnish the best examples, shows that there is nothing in their connections or relations which need necessarily interfere with their complete removal. Precise information as to the presence and attachments of these growths we may now obtain with comparative safety. Whether their removal is to follow upon their discovery will be matter for further consideration.

With the view of extending our knowledge of these growths, a committee of this Association is occupied in collecting information relating to them. The report of this committee will, I hope, form the basis of an interesting discussion in the pathological section which will be opened by Mr. Paul.

I now come to speak of the prostate, and I shall do so in reference to the part it takes in obstructing micturition, for the reason that it is this symptom which in some form or other brings the patient under our care.

It appears to me that enlargement of the prostate is specially interesting to us in relation to it earliest and to its most advanced forms, and it is to these points that I shall more directly refer.

If we take the obstructive disorders of the urinary apparatus, and inquire what feature of them is most detrimental to the associated parts the answer undoubtedly will be, The misdirection of the muscular force that is thereby entailed. How can we explain the structural alterations which take place behind the obstructed point, and which manifest themselves in different ways, except as the results of urinary retention and retrograding pressure? How frequently do we find, in cases of stricture or enlarged prostate, that the whole of the apparatus behind the primary constriction consists of little else than dilated saccules and tubes? Is not this distinct evidence of back-pressure going on, though it may be imperceptible, from the moment that impediment arises to the escape of urine from the bladder? The more we study animal mechanics, either in their physiological or pathological application, the more can we appreciate the truism that force is never lost. If it is not permitted to act for good, it must be productive of evil; if it is not exerted towards the legitimate fulfilment of a normal act, it must inevitably exercise a corresponding pressure in an abnormal direction. Whenever I see in the post-mortem room an ordinary specimen of dilated kidney, tortuous ureter, or sacculated bladder, associated with an enlarged prostate, or a stricture, the expression "misdirected force" almost involuntarily escapes from me.

Such considerations as these have long led me to believe that our treatment of prostatic stricture—or by whatever name we know it—commences, as a rule, far too late; we delay until the bladder shows, by the formation of a pouch, or a saccule, behind the prostate, the first bad influence of back-pressure before we seek to rectify it.

I have endeavoured to prove how much good may be done by the adoption of judicious mechanical treatment on the appearance of indications that the prestate is commencing to obstruct micturition, and I have founded my suggestion upon a condition which may be seen illustrated in any museum—viz., one in which, though the gland has become large, obstruction has not been known to occur. An extended adoption of this practice has convinced me that the pressing symptoms connected with an enlarging prostate may be kept in abeyance by the timely employment of those principles of treatment which are generally recognised as being applicable to any tubes within the body which are threatened with occlusion, and are within our reach.

In the more advanced forms of prostatic enlargement, where the bladder has been converted into a receptacle little better than a chronic abscess in which urine stagnates, surgery has done much to afford relief.

When the comfort that catheterism is capable of affording has ceased to be effectual, other plans of establishing a drain for the urine are at our disposal. It is not necessary that I should discuss the various means of effecting this; let me, however, say a few words in reference to two which have more recently come under notice: these are—first, incision into the bladder from the perineum; and, secondly, paracentesis through the enlarged gland.

For the purpose of securing a more or less permanent channel for the escape of urine from the bladder, other than by the urethra, I must admit that, following the practice of Syme, and to some extent of Edward Cock, I have a decided preference for an incision through the perineum, on the twofold ground of safety and comfort. We have had numerous examples of the great benefit that cystotomy is capable of affording for bladder affections dependent on a large prostate—none perhaps more striking than the case narrated by Mr. Lund on the memorable occasion of the meeting in London of the International Medical Congress. The paper closes with this observation: "I have thus placed on record this case, unique in its character, and interesting and encouraging in its results, with the hope that should a similar case occur to any surgeon now present, he will not hesitate to give his patient the chance of benefit from a course of procedure so simple in its nature, and so likely to be followed by temporary, if not permanent, benefit." (*a*)

I may be permitted here to submit to your notice a method of puncturing the bladder through the enlarged prostate which has afforded very gratifying results. It consists in passing the trocar through the gland, and retaining it in the perineum, so as to afford a permanent as well as a convenient drain for the urine. I should have had more diffidence in commending this operation to your notice had it not received the approval of our distinguished Associate, Professor Gross, whose contributions to the Surgery of the Urinary Organs are held in deservedly high repute on both sides of the Atlantic.

Though the primary object of cystotomy, as usually practised, is merely to place the bladder at rest by providing a continuous drain for the urine as well as the products of cystitis, it occurred to me, as it had already done to others, that it would be possible to extend this proceeding, with the view of removing those barriers to micturition which the hypertrophied gland so frequently presents.

It was to meet conditions such as these that Mercier introduced and practised division of the prostatic bar by means of a cutting instrument introduced along the urethra. This plan, though admirable in its conception, was open to the objection that in its execution it was necessarily uncertain, there being no means of surely ascertaining that the section

---

(*a*) 'Trans. International Medical Congress," vol. ii.

was confined to the obstruction to be removed. On carefully considering the position of matters, as well as the proposals that had been made, it appeared to me more reasonable to attempt to divide the prostatic obstruction at the neck of the bladder from an opening made into the membranous urethra, than by means of instruments which had to traverse the whole length of the canal. I have recently brought under notice a case (a) in which I thought it desirable to explore the prostatic urethra from an opening made in the perineum, and through which I was enabled to divide with precision a prostatic barrier. The division of this portion of the gland was followed by complete restoration of the power of micturition, and has so far proved of permanent advantage.

The proceeding which I have thus put into practice seems first to have suggested itself to Mr. Guthrie, but I cannot find that he ever employed it. That it is not identical with the somewhat extensive incision of the prostate as for lateral lithotomy which was practised by Sir William Blizard is at once obvious. Its aim is to divide the obstruction—and the obstruction alone—by an opening so planned as not to expose the patient to undue risk; whilst, at the same time, it is capable of affording the greatest amount of room for manipulation by an extension of the incision, should this be found to be necessary.

I need hardly observe that a proceeding of this kind should be undertaken before the bladder has passed into a condition of confirmed and irremediable atrophy; otherwise, though we may succeed in removing an obstacle to the introduction of the catheter, our prospect of restoring the power of micturition will be as hopeless as it has proved to be under somewhat similar circumstances where the operation of lithotomy has been undertaken.

It is impossible to avoid the conclusion, from their examination after death, that many atonied bladders might have been prevented becoming so by the timely removal of the obstruction by which a condition of permanent paralysis was induced and maintained.

The operative treatment of the enlarged prostate, when it obstructs micturition to a degree that cannot be met by judicious catheterism, is yet, I believe, open to considerable improvement.

Though the literature relating to either complete or partial excision of the prostate is very limited, there is much in it of promise. In one case, where I extirpated the whole gland for malignant disease, the benefit that followed far exceeded my expectations. It was that of a middle-aged man who, by reason of a carcinomatous prostate, was threatened with a speedy and painful death. I cut down upon the gland in the median line, and succeeded in enucleating it tolerably cleanly with my finger. I saw this patient eight months afterwards in very fair health, and quite able to go about his business. So far he has enjoyed an immunity from the symptoms which induced me to perform this operation, and though his disease is a malignant one, we have every reason to be content with the results obtained.

Then we have numerous examples where considerable masses of the prostate have been removed with very great advantage in the course of operations on the bladder. Amongst these I would specially mention an important case by Mr. Bickersteth (a); and, more recently, another by Dr. John Ashhurst, of Philadelphia, in which the whole of an enlarged third lobe was successfully removed.

Cases such as these seem to favour the hope that operative surgery will be found capable of affording more relief to exceptional instances of this kind, and of extending to the large prostate the treatment which in some degree is applicable to other deep-seated growths.

Passing to the urethra, I would again take the opportunity of adverting to the value of Otis's work in regard to the dimensions and dilatability of this canal; if he had done no more than contribute to the improvement of lithotrity—and this cannot be questioned—we should still be largely in his debt. I cannot, however, follow him in his views relating to the performance of internal urethrotomy as a means of treating stricture of the urethra. My impression is that this operation is losing instead of gaining ground in the opinion of many who have ample opportunities of judging fairly of its merits. That it is an operation fitted for the treatment of stricture in its early stage is a conclusion I am disposed to take exception to, on the ground that it is neither necessary nor safe as compared with other methods. I believe that in its early stage stricture may be successfully combated by the employment of thorough cleanliness combined with the judicious use of dilatation, as we are accustomed to practise it in this country.

If internal urethrotomy gave a greater immunity than other operations from a recurrence of stricture, or did away with the necessity for subsequent mechanical dilatation, then, perhaps, with the view of avoiding other risks to which all persons suffering from stricture are liable, I might feel more disposed to employ it. But as such is not the case, and the risk attending its performance is not inconsiderable, I cannot concede the importance which is claimed for it by its more ardent admirers. That internal urethrotomy in some cases is a necessity—as by it we are enabled to redner amenable to treatment a stricture heretofore intractable—I am willing to admit, but to recommend it as capable of effecting a permanent cure is quite another thing.

The treatment of impassable stricture of the urethra has received an important addition by the practice which Mr. Wheelhouse has introduced, the great credit of which he seems desirous rather of sharing with his surgical colleagues than of appropriating to himself, as I see he always refers to it as the "Leeds operation." Like other conditions which may be spoken of as relative to something else, rather than as fixed or defined, the impassable stricture is, I believe, gradually becoming rarer, a circumstance which is largely due to the great improvement that has taken place in the construction of instruments specially adapted to their treatment, amongst which I may mention the filiform bougies and the tunnelled instruments of Gouley, of New York. For the purpose intended, I do not think there is any proceeding equal to that which Mr. Wheelhouse has introduced and I have no hesitation in including it amongst the improvements to which I am now referring.

Permit me, without apology, in this mechanical age, where invention after invention for the treatment of stricture comes upon us with marvellous rapidity, to claim a moment's consideration for what Mr. Savory has called the medical aspect of this question. We all know what irritation is: there is such a thing as irritation of a stricture, either by what passes through it naturally or is introduced to correct it. Let us not disregard, as a principle of our treatment, the importance of securing for the urethra that physiological rest which the late Mr. Hilton wrote so well.

The question may here very properly be asked whether, in our search for novelties as improvements in treatment, we have discovered any new diseases, the better management of which, by reason of our acquaintance with them, we may in all fairness leave to our descendants to determine. The admirable Bradshaw Address of Sir James Paget will no doubt have the effect of quickening our perceptions in this direction.

Though I cannot point to any discoveries of this kind as affecting the region which is now occupying our attention, I may note one gratifying result of extended clinical and pathological investigation: I refer to the juster assignment of symptoms to the causes producing them—symptoms which not very long ago were looked upon as constituting independent diseases. But if we have not discovered any new diseases, we must remember that varying circumstances may at one time add intensity to some disorders and considerably modify the progress of others. I have a strong impression that the times through which we are passing, characterised as they are by the production of great and continuous nerve tension, have brought into prominence a state of brain-strain which is apt to show itself in any organ which may happen to be deranged or is overtaxed.

A recent author seemed rather to conclude that tension of this kind was most injuriously felt and shown by our American cousin, whilst the Britisher, for some reason or other, was less influenced in this manner. Whether this be so or not I am not prepared to decide, but I am disposed to believe that purely nervous affections—affections associated, as far as we can determine, with no obvious structural alteration—are more common than they used to be. That they occasion much distress, and cause persons who suffer from them to be unduly apprehensive, will be generally admitted. Nay, further, by their mimicry of more certain diseases, they induce a condition of anxiety which is often intolerable. It is well, too, to bear in mind that the interpretation of symptoms, as also their prevention and amendment, are frequently to a large extent dependent on a recognition of the possible existence in a patient of exaggerated nerve tension.

(a) *British Medical Journal*, June 9th, 1883.
(b) Trans. Royal Med. Chir. Society, 1882.

Before an audience of this kind it would be presumptuous on my part further to indicate in detail the many improvements that have taken place in the treatment of the surgical disorders of the urinary organs; further, where there have been so many contributors toward this progress it would be invidious for me to particularise.

Let me, however, in common fairness to those to whom we are much indebted, say one word in reference to the advance that has been steadily made in the construction of the means and appliances used for these purposes.

I can remember some instuments which five and twenty years ago, or even less, were regarded as improvements, but have now passed into obscurity or to the shelves of the museum. In no department of applied mechanics has greater perfection been obtained than in that of the surgical mechanician, and nowhere is this better illustrated than in the instruments employed in the treatment of urinary diseases.

It seems almost ungenerous, after referring to several proceedings of an operative kind, the doing of which entail pain and involve risk for the sake of advantages to follow, that I should allow to pass unnoticed the work of those who have removed the one and lessened the other. In chloroform and anæsthetics we have a priceless boon, without which surgery would long ago have been at a stand-still, and many persons now living in comfort and enjoyment would ere this have ceased to exist. I am not old enough to remember the pre-anæsthetic age, and, therefore, am unable to draw a contrast which will be a vivid one to some of the "elder brethren" I am addressing to-day. I am reminded, however, of an incident bearing upon such a contrast, which, with your permission, I will briefly relate.

Some two years ago, a sea captain, a patient of mine, and by no means a bad amateur doctor, on returning from sea, told me somewhat gleefully that he had successfully performed an amputation. Whilst his ship was at Ruruta, an uncivilised island in the South Pacific, a poor native got his arm entangled in a sugar-crushing machine. As there was no doctor on the island, my friend the captain was summoned, and at once saw the necessity for removing the shattered fragments of the limb. The shrieks and struggles of the powerful aboriginal were most fearful. Recognising the necessity for taking steps to save the man's life, the captain hurried off to his ship, and returned with the necessary implements, together with a quart of the newest and most potent rum. In the absence of chloroform he induced his patient to swallow this fiery compound, wineglassful after wineglassful, until intoxication was induced, and subsequently profound alcoholic insensibility. Then the tourniquet was applied, and amputation successfully performed. Recovery rapidly took place. So pleased was the savage with the effects of anæsthesia that he subsequently offered to let my friend cut off some of his toes provided that the process of inducing insensibility was repeated.

Next in importance to chloroform and anæsthetics are those means which have been recently promulgated for diminishing some of the greater risks contingent upon wounds and surgical operations. About antiseptics, I desire to speak in no uncertain terms. Though our views may not be unanimous, though some of us may be sceptical about the import of germs and of sprays and other details, can we doubt that when the surgical historian of the nineteenth century has to recount the men as well as the measures that have favourably influenced the progress our art has made, the name of Lister will occupy a conspicuous place?

I have now done: it has not been my ambition to hold up to you a golden calf: to attempt to dress it in flowers of rhetoric and to ask you to worship it. I have rather endeavoured to remind you of some of the directions in which surgery is now travelling and to estimate in a measure the pace at which it is going. It is impossible to engage in a work of this kind without a full conviction that though our art is an imperfect one, it is distinctly a progressive one. In the course of your visit to this, which has been aptly referred to as the second city of the Empire, you will find almost all the arts and sciences laid under contribution for the development of commercial enterprise. And the activity displayed in the promotion of trade and commerce will probably suggest the inquiry whether *we* are equally progressive, whether we are in correspondence with the times in which we live.

There need, however, be no hesitation in asserting that, whether we are regarded as preventers of disease or as practitioners of medicine or of surgery, every one of us in his daily practice is constantly demonstrating that, year by year, something additional is contributed by our profession to the comfort and the life of man.

◆

France.

[FROM OUR SPECIAL CORRESPONDENT.]

Animal and Human Vaccine.—The Académie de Médecine in 1870 instituted an inquiry as to the relative value of vaccine taken direct from the cow and that taken from the child, or animal and human vaccine, the result of which was the unanimous opinion that animal vaccine was decidedly inferior when kept for some time, as its power of transmission was considerably weakened. M. Blot has addressed a report to the Government on the subject, in which he cites a case which leaves the question without any doubt. It appears that the Académie sent out to a doctor practising in the Ile de la Réunion a certain number of tubes of animal and human vaccine. Inoculations were made with both kinds on persons never previously vaccinated. *All* the vaccinations practised with the animal vaccine failed without exception, whereas all the others were successful. Consequently, if, according to M. Pasteur, the active principle of the vaccine is to be attributed to little organisms, it must be inferred that the contents of these vesicles is a liquid unfavourable to the culture of the microbes.

Ovarian Cysts.—At the Société de Chirurgie M. Terrillon made a communication on ovarian cysts partly enclosed in the broad ligament, and the consequences of this disposition as regards ovariotomy. He reported three cases of this sort the ablation of which was attended with great difficulties. Cysts developed at the expense of the ovary were easily removed when pediculated, but the reverse obtained where adherence existed, for the tumour, instead of floating freely in the abdomen, becomes infiltrated, so to speak, between the walls of the broad ligament. The result of this disposition was that the cyst was kept in direct contact with the sides of the uterus, the bladder, and the vaginal *cul de sac* on the one hand and the iliac vessels and nerves with the pelvic walls on the other. At first a lax cellular tissue is all that intervenes, but later on adherences unite the different parts, a circulation common to both establishes itself, and their section cannot be made without causing a great loss of blood. The walls of the broad ligament become also so thickened that their separation after operation is not only difficult, but often impossible. The diagnosis of this position is, although very difficult, not impossible, especially when proper attention is paid to the position of the different organs. He considered the prognosis to be very grave, on account of the absence of the pedicle, as the whole of the tumour cannot be taken away, thus exposing the patient to divers accidents, or a relapse of the cyst. As to the after-treatment, he would insist on the necessity of placing drainage tubes wherever necessary, and large washings out with boric acid or phenic acid lotions. A discussion followed, in which M. Terrier and others took part. M. Terrier insisted on the necessity of enucleating as effectually as possible the cyst, while M. Pollaillon, who quite agreed with what had been said, mentioned the English method of dealing with such adherences, which is, not to continue the operation, but to be content with the incision of exploration, which is not in itself dangerous. M. Monod cited a case in his own practice. The diagnosis was fibro-cystic tumour of the ovary. The operation was attended with extreme difficulty, as there seemed to be a regular fusion between all the parts. After emptying the sac, the greater part of the tumour had to be left; yet the patient made a good recovery.

Use of Lead in the Manufacture of Perambulator Coverings.—The Sanitary Board of Paris has caused a serious inquiry as to the matters which enter into the composition of the coverings of perambulators, and it has been shown that preparations of lead are largely employed in their manufacture, so much so that the Board has thought fit to address a report to the Prefect of Police requesting him to forbid the employment of toxic salts in the manufacture of the oil-cloth used so largely for these little carriages. Extending their researches, the Board caused the oil-cloth to be examined which so often covers the dining-tables in Paris. The result of the analysis has been that in one of these table-cloths of good description ten ounces of metallic lead was found in each square yard.

Resection of the Lung.—Professor Ruggi, of Bologna (Italy) last week successfully performed the above operation. His patient was a woman, æt. 27, attacked with tuberculosis, with almost complete disintegration of the upper half of the right lung. M. Ruggi proposed ablation of the organ, and, the woman consenting, the operation was performed by the surgeon, assisted by a young doctor of rising talent. The whole of the upper lobe was removed, and a part of the middle one. The patient bore the operation well, and is now in a satisfactory condition. Although the above operation has been only reported by one of the daily papers, it is to be hoped that it will not turn out to be another Koch and bull story. As to the *modus operandi*, details are wanting.

British Medical Association.

The fifty-first annual meeting of the British Medical Association, held at Liverpool, will leave its mark upon the history of the organisation, not only because of its marked success as a medico-scientific assembly, but especially because of the important measure of reform in the constitution of the Association which was then debated and adopted.

ENTERTAINMENTS.

All the circumstances combined to make the meeting a success, although many of the most distinguished members of the Association were conspicuous by their absence, and the Foreign visitors were sparsely represented. The weather was all that could be desired. The College buildings were most commodious, and in all respects fitted for the reception of so large an assembly; and the earnestness of the medical men of Liverpool and vicinity bore fruit in the perfect working of the arrangements and the consequent complete satisfaction of the visitors: everything, indeed, which our Liverpool hosts could do to extend a cordial and profuse hospitality to their brethren was done, and well done; but it was apparent that the citizens and civic authorities of so great a town as Liverpool might have taken a larger share than they did in Association hospitality. The public entertainments were two in number, one of which—the *soirée* in the Art Gallery—was given by the profession; and only one—the *soirée* by the Mayor, at the Town Hall—was afforded by the citizens. The Art Gallery *soirée* was a splendid affair, well devised and admirably managed, and it was attended by an immense crowd of the gentry of the town and their families. The Art treasures were a great attraction, the music excellent and diversified, and the refreshments abundant.

The Mayor's *soirée* had the advantage of being held in the Town Hall—a splendid building of the last half century—but, in other respects, it was not comparable with the Art Gallery entertainment, the refreshment department being especially deficient.

The great steamship companies acted with much generosity toward the Association, the White Star, Anchor, and Cunard lines having thrown open their splendid ships *Republic*, *City of Rome*, and *Servia* to inspection, and having provided luncheon on board each day for large parties of visitors. Messrs. Laird also opened their ship-yard to inspection, and the Mersey Tunnel Company admitted a large party to a most interesting but very dirty subaqueous exploration of their works.

The Saturday excursions were five in number, and were held under very favourable circumstances. The first was to Llandudno and Conway by steamer, and to lunch in the old banqueting hall of the Castle, the North Wales branch being the hosts. A very large party also visited the Duke of Westminster's seat at Chester-Eaton, and dined on their return at the Grosvenor Hotel. A party was also conducted to Southport and Blackpool, under the management of Mr. George Walker. At Southport an elegant breakfast was provided by the local members of the profession, and subsequently, after the excursionists had reached Blackpool by steamer and rail, they were entertained at dinner by the directors of the South Shore Hydropathic Institution.

To Lancaster also a small party went, where they were entertained at luncheon by the local medical men, and shown the Castle, the Royal Albert Asylum, and other places of interest. Lastly, a river excursion was planned by Mr. Bickersteth, who took his party by steamer seawards for a few miles, so as to give the visitors a view of the coast, on its return visiting some of the New Docks, and then steaming up the river for some miles towards Runcorn. The private hospitalities were profusely generous, and the universally-expressed feeling was that the Liverpool profession had carried through one of the most successful meetings of the Association for many years past.

The public dinner of the Association was a splendid success. It came off in the Philharmonic Hall, and in the presence of over 200 ladies, who were admitted to the galleries, and as about 350 members sat down, and the room was beautifully decorated, the scene was very brilliant.

ADMINISTRATION AND ORGANISATION OF THE ASSOCIATION.

The meeting will be recollected as an important epoch in the history of the Association, because of the important changes in its constitution and in the *personnel* of its executive which have been effected on this occasion. The reconstitution of the administrative body which was decided upon at the Worcester meeting this time last year was embodied in a series of alterations of bye-laws brought up at the Liverpool meeting and carried without substantfal change. That reconstitution aims at the more efficient direct representation of the branches in the Council, provides for the popular election of such representatives, and for the enlargement of the powers of the Council so elected, the influence heretofore exercised by the committee of Council and by the *ex-officio* members of the Council itself being in great measure transferred to the newly-elected representatives. This reform is worthy of the unqualified approval of those who look forward to make the Association more powerful and more popular than it has heretofore been, because—if it effects no other purpose—it will create in the branches and in the individual members an interest and an active co-operation in the affairs of the body which could not exist as long as its policy and its administration were in the hands of self-elected councillors, however earnest they may have been. In the time which has now passed the branches might talk and might pass resolutions, but they had no effective means of making their voice heard or their influence felt, and consequently much has been said and done by the Council and by its committee not only in reference to the internal administration, but in the public policy of the Association, which has been directly contrary to the will of the members at large. We may illustrate this statement by the relation past and present of the Association to the Compulsory Notification legislation. For many years which followed the inception of this legislation, the profession at large were kept in profound ignorance of the proposal to put them under the yoke; the branches knew nothing of it because they had no representatives whose duty it would be to watch legislation, and the Journal, being without any official authorisation, pledged to a support of the proposals of the notificationists, was significantly silent on the matter. But the moment that a few individuals took it upon themselves to inform the profession as to the nature of the proposals of sanitarians the voice of the Association was loudly heard in condemnation of those proposals, and the policy of inaction and of covert support was at once reversed. Had the reform which has now been effected taken place five years ago the representatives of branches would have at once raised the alarm, and the risk to the profession of being burthened with the duty of compulsory notification would not have been run.

Those seniors in the executive of the Association who have heretofore been endowed with the chief influence in its management, and who believe that "what is is right" are, as might be expected, of opinion that the incursion of elected representatives is a vital mistake, and that the *status quo* is everything which could be desired, and this sentiment made itself manifest in a tacit opposition to a proposed discussion of new bye-laws. It appears that the Articles of Association stand in the way of the proposed reform, and it was, therefore, not competent for this meeting of the Association to adopt the new bye-laws until, as has been arranged, the Articles of Association have been submitted for alteration in legal form to a general meeting of the body in London on the 17th of the current month. The members, however, insisted on discussing, provisionally, the proposed changes, and thus a full understanding was aimed at which will need only to be formally approved at the adjourned meeting.

PAYMENT OF REPRESENTATIVES.

A further proposition of reform was made to the meeting to the effect that the Association should pay the travelling expenses of representatives of distant branches. Great differences of opinion existed as to the practicability and expediency of this proposal: on the one hand it was urged that, if this facility be not afforded to delegates to come to London, they could not reasonably be expected to make the journey, and the administration will thus remain chiefly in the hands of the metropolitan members; on the other hand, it was contended that the expense of such subventions would be very heavy, and that, if it were not, the proposal would be objectionable, because it would place men of inferior position in the representation of branches. The proposal was not adopted, and we are, on the whole, satisfied that it was not. We think it as well that the Association should have experience of the working of direct representation before it adopts a system which would undoubtedly cost a considerable sum and might complicate the early working of the newly-altered bye-laws.

HOMOEOPATHY AND THE CONTAGIOUS DISEASES ACTS.

Two of the general meetings were diversified by a very clamorous debate on these subjects, and a condition of disorder reigned for a portion of the sittings which was not creditable either to the good sense or good manners of the members. A change of bye-law to prohibit the admission of avowed homœopaths or open advertisers was offered by Dr. Nelson Hardy, which met with such vigorously and clamorously expressed support that its opponents could not obtain a hearing, and the attempts of numerous members to speak all at the same moment produced complete confusion and much uproar. Eventually Dr. Hardy's resolution was declared lost; but the division was taken amidst so much noise and excitement that no one could say what decision it represented. A demand for a poll was immediately drawn up and signed, but it was found unnecessary to present it to the Chairman, it having been agreed by the Council that the opinions of the branches should be elicited with a view to further consideration of the subject next year. There can be no reasonable doubt that the branches will declare almost unanimously against the admission of homœopaths, so that the adoption of a prohibitory bye-law may be expected next year.

The Contagious Diseases Acts came under notice by means of a resolution offered by Dr. Fitzpatrick on behalf of Dr. Charles MacNamara, directing the Council to take steps to prevent the repeal of the Acts, and to restore them to a condition of effective operation. The resolution had the support of the entire meeting, save three or four gentlemen, who, essaying to speak, were howled down in a very rude and discreditable manner. Without hearing them, the resolution was adopted.

In the interest of the Association, of the profession, and of the party who were guilty of this clamour, we greatly regret these proceedings, and trust that the meetings will not again be disgraced by them. It may well be questioned whether it is good taste for speakers to obtrude their observations when it is evident that the meeting is unwilling to hear them; but, if they desire to do so, it is not only irregular and discreditable to shout them down, but very foolish as a matter of policy, for it strengthens their case, and gives them a grievance more powerful as an argument before the public than any other they could adduce.

The beginning and the end of this regrettable disorder was, in our opinion, the way in which the business of the Association is crushed into one or two necessarily limited sittings. It is a part of the system of the Association to devote two or three hours each day to the hearing of addresses of enormous length, which in many instances are inaudible, and generally wordy and uninteresting, and which might, with much greater advantage, be delivered at the openings of sections, and read by those interested in the columns of the succeeding Journal. To make room for these disquisitions—though generally of a high order of merit, but wofully out of place—the most important work of the Association is crushed into a few minutes.

On this occasion the Medical Bill, the Compulsory Notification Bill, the Habitual Drunkard movement, and a host of other matters of the greatest moment to the profession were hurried over without anything like due consideration; and it is not wonderful that, when it was desired to hurry on to next business, the meeting should be clamorous in opposing debates which would cause delay.

THE SECTIONS.

The sectional work, as we predicted last week, proved very attractive as a whole, whilst some special papers and discussions called forth an unwonted display of interest that proved that the various programmes had been made up with great judgment. As might have been expected from the array of papers down for reading, a great number had to be taken as read, there not being sufficient time to give every one a hearing. This would have been the case even if no time had been wasted, but not, of course, to so great an extent as was actually the case. The work, as a rule, did not commence promptly to time, as business and other meetings were timed for the same hour as the commencement of the daily sectional work. By delaying the sectional work, on account of those desirous of attending general meetings, the number of expectant readers who suffered disappointment was materially increased. Still another cause was operative in this direction. Several gentlemen sent papers who were unable to attend personally; and in some instances these were read by the sectional secretaries. This was the cause of not unjustifiable complaint on the part of some disappointed ones, as they considered that gentlemen who took so little interest in their papers that they were unwilling to put themselves to any inconvenience for the purpose of reading them should not, at any rate, have precedence given to them to the exclusion of others who had not only taken the pains to write papers, but also made sacrifices in order to be present to read them.

With this exception the work was carried on in a way that gave universal satisfaction. The discussions were conducted harmoniously, and when speakers differed from each other, convictions were expressed in a manner to which no exception could be taken.

MEDICINE.

All the discussions in this Section were of an important nature, and excited much interest. Perhaps the crowning interest was that which centred in that on Aphasia, which was opened by Professor Gairdner, of Glasgow, which provoked an animated and well-sustained discussion.

SURGERY.

The President's Address in this Section was somewhat of a surprise, bearing as it did on subjects usually included in the term public health rather than on that of surgery proper. It was good of its kind, however, and as such was well received. The discussion on Surgical Diseases of the Kidney, and operations for their relief, opened by Mr. Clement Lucas, and that opened by Professor Parker, on Intestinal Obstruction, by or without Operative Interference, gave rise to animated debates, the latter especially being specially commented on, from the attitude of masterly inactivity being insisted upon by the introducer in certain stages of obstruction.

OBSTETRIC MEDICINE.

In this Section four subjects came on for discussion. With regard to that on Total or Partial Extirpation of the Uterus for Malignant Disease, the balance of opinion seemed to be, as one of the speakers put it, that the operation of total removal would have to show better immediate results, and also better permanent results, before it could take its place by the side of other operations by abdominal section. The discussion on Operative Treatment of Uterine Fibromata, Hysterectomy in extreme cases, found a powerful advocate in Mr. Knowsley Thornton; but the general impression was that such an operation was but rarely called for, and that in the immense majority of cases patients could be tided over the climacteric without subjecting them to the hazard of such grave operations. The discussion on Metria, in which fifteen or sixteen members took part, might have been carried on for an indefinite time, had circumstances permitted, and was the means of showing the very varied views that are still held on this subject, and also of showing how liable individualsare to be led captive by their own single ideas. If people were in the habit of holding the ideas of others as worthy of as much consideration as their own, the ground on this subject would be very much cleared; but as things are, much will have to be done in it before anything like unanimity of opinion prevails, and this not so much from want of data upon which to found correct opinions, as from the tendency there is amongst many to be so filled with their own ideas that they have no room for more. The fourth subject—that of Porro's operation—was chiefly remarkable for the very able and complete survey of the subject in all its bearings as contained in the opening paper by Dr. Clement Godson. It elicited universal admiration and deserved compliment from every speaker, Mr. Lawson Tait remarking that for the future the operation should rather be called Godson's than Porro's.

PUBLIC MEDICINE.

The activity in this Section was also great—greater perhaps for the reason that such a number of untried fields still remain to be cultivated. All, or nearly all, our surroundings are still in an unsanitary state; and there is scarcely any direction in which we can look in which we are not impressed by the amount that remains to be done, rather than by what has already been accomplished.

Professor Humphry, F.R.S., of Cambridge, has accepted the Presidentship of the Sanitary Congress, to be held in Glasgow next month.

Our contributor, Mr. G. P. Field, whose paper "On Catarrhal Diseases in Children" appeared in our last issue, has been elected Dean of St. Mary's Hospital Medical School.

The Rolleston Memorial Fund reaches £1,200, and has been delivered over to the University of Oxford to found a prize for original research in animal and vegetable morphology and physiology, which will be awarded every two years.

Owing to an excessive death-rate from diarrhœa and measles, Berlin is yielding the epidemic mortality of 66 per 1,000 of its population; whilst Munich, Buda-Pesth, Hamburg, and Breslau exhibit almost equally unhealthy returns. No fewer than six hundred and twelve deaths occurred in one week from diarrhœal diseases in Berlin alone, exceeding the mortality from this cause during the same period of the whole of the United Kingdom.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 21, Madras 36, Paris 23, Geneva 20, Brussels 24, Amsterdam 24, Rotterdam 19, The Hague 30, Copenhagen 23, Stockholm 28, Christiania 19, St. Petersburg 28, Berlin 66, Hamburg 40, Dresden 31, Breslau 42, Munich 46, Vienna 29, Prague 34, Buda-Pesth 43, Trieste 21, Turin 26, Venice 29, Lisbon 27, Philadelphia 29, Baltimore 35.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

Subscriptions for France are received by Messrs. Bailliere, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

Subscriptions for Russia are received by Messrs. Rajchman and Frendler, 18 Senatoren Street, Warsaw—post free £1 5s. 0d. per annum.

Subscriptions for the United States are received in New York by Messrs. Willmer and Rogers; Philadelphia, by Dr. Brinton: post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-Office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 8, 1883.

RETROSPECT AND PROSPECT.

The presidential address of Dr. Waters to the British Medical Association will commend itself to every one who carefully studies its periods, as a legitimately hopeful survey of the achievements and possibilities of medicine.

It is ever a grateful task to recapitulate the triumphs achieved by the profession in past times; and notwithstanding that we have to take cognisance also of undoubted errors which have been attendant on misconception and ignorance, still the general result of historical progress is grandly testimonial to the disinterestedness and devotion of medical men to the principles of their calling. The theme afforded to him who describes the onward march of scientific medicine is sufficiently inspiring; and we cannot be other than enthusiastic when there are reiterated before us the frequent conquests of our art over its enemy disease. It matters not that the story has been told before, or that its burden is familiar in our ears as household words; it awakens at each fresh repetition the same enthusiastic pride, because it serves unceasingly to remind us that there is a brotherhood in medicine, by virtue of which each member of the profession shares, not only in its work and danger, but in its higher and more spiritual rewards.

That Dr. Waters has fathomed the sympathy that unites the practitioner with the scientific inquirer, his utterances to the Association most clearly show; that he is himself a zealous cultivator of the most progressive science, his previous work has already plainly proved; and hence it is that no more fitting exponent of the truths expressed in his address could have been found to urge the growing need for other and greater exertions in the battle with the unknown factors of disease. He has sounded a note that should reverberate throughout the complete ranks of the profession; that should be accepted by every member of it whose aspirations look beyond the present day attainments; and to the command it enforces should be yielded implicit obedience by all to whom the sacred name of progress acts as a stimulus to exertion. Dr. Waters has put most clearly forward the importance of a study of heredity to a comprehension of disease, and to appropriate treatment with a view to aborting it; and in connection with the relation between slight functional disturbances and the commencement of organic lesions, he rightly insists that a proper appreciation of such phenomena in their initial stages may secure the preservation of life. In his own words, "Although we stand almost powerless to arrest the course of confirmed structural changes, there can be no doubt that, could we recognise the earliest steps in these changes, could we see clearly the points of departure from normal conditions in various chronic and hitherto incurable maladies, we might do much to check these alterations of structure, and prevent any further progress of the disease." Whether or not such increased powers will result to the next or succeeding generations of practitioners, as a consequence of the labours now being undertaken by workers of our own era, is the conjectural topic of much of Dr. Waters' further remarks; but that he is accurately correct in the opinion he has expressed as to the direction in which such advances must be made, is incontrovertible. "In an investigation of this kind, our hospital work," he says, "is comparatively useless. There we are brought into relation, for the most part, with disease already well marked—disease which has produced its easily recognisable results; and if patients present themselves with slight symptoms, they perhaps soon recover, and are lost sight of. It is in the daily work of private practice that observations such as I have referred to can alone be satisfactorily made, and it is therefore to the great bulk of practitioners throughout the country that we must look for aid in this matter. It involves a lengthened study of each individual case; a close watching, not for weeks or months, but for years; and perhaps the facts gathered in a lifetime might be but few. It relates to the consideration of subjective symptoms which we cannot accurately estimate with our present physical means, but which are intimately associated with individual peculiarities and idiosyncrasies, and often form the most important elements in our diagnosis, prognosis, and treatment. It may be that, with more refined instruments of precision, and greater scientific knowledge, we shall bring many of these symptoms within the range of physically recognisable facts." This hope it is that animates the majority of earnest seekers after truth; and the spirit of persistent inquiry to which it gives rise is what we are mainly indebted to for all the brilliant improvements undergone by treatment and leading to prevention in recent times.

Dr. Waters' address is an earnest exhortation to renewed endeavour. It wisely offers prospects of future successes comparable to, and justified by, the fruitful outcome of precedent work. It clearly indicates the lines along which those who will may pass to useful ends; and, taken as it is intended that it should be, it will serve an invaluable purpose by stimulating the labours of the many younger men whose chief desire is to advance with the profession they are assisting to become a more perfect engine for perfecting human happiness.

◆

THE MEDICAL BILL.

A deputation representing the Scottish Universities in the person of graduates who practise in London was received by Mr. Mundella last week. The deputation consisted of Sir Andrew Clark, Dr. Dyce Duckworth, Dr. Potter, Dr. Wight, Mr. A. T. Bateman, Dr. Glover, Dr. Barnett, Dr. T. Spencer Cobbold, Mr. Davy, Dr. Johnson, and Dr. Stevenson, and was accompanied by Sir Lyon Playfair, M.P., and Mr. Jas. A. Campbell, M.P. Dr. Dyce Duckworth pleaded the superiority, in educational *prestige*, of the Universities as against the Corporations, and Sir Andrew Clark expressed his regret at the removal of the column intended for registration of the higher titles in the Medical Register.

Mr. Mundella said this was the twelfth or thirteenth deputation he had received already, apart from those that he had had the honour of receiving jointly with Lord Carlingford. Of all these deputations only one had expressed real opposition to the Bill, and that was the least important and the least representative of them. He agreed entirely with what had been said by Dr. Duckworth and Sir Andrew Clark as to the importance of the preponderance of the University representation upon the divisional body in Scotland, and the Government would insist that the Universities should have the preponderance. There might be some difference as to the precise proportion of that preponderance, and they might have to come to some arrangement in order to enable them to pass the Bill, driven as they were into a corner by time and the exigencies of their position. He hoped, and, indeed, was anxious, to pass this Bill; and he meant to pass it this session, if it were within the range of human possibility; yet he would rather not pass it than sacrifice its important provisions. He still hoped and believed that in the present month he would get this Bill through the House of Commons. The Government would carefully consider what Sir Andrew Clarke had said as to the registration of higher titles. It was much to be regretted that, on a measure which had for its main object the interests of the public, and, next, the higher education and higher *status* of the profession, the whole battle had ranged round this miserable question of representation of corporations. It was deplorable that men engaged in such a noble work should come there for no other purpose than to preserve beggarly vested interests.

We cannot but regret that the future of medical reform should be in the hands of a minister who appears to be unable to take any extended view of the subject with which he is called upon to deal. It may possibly be discreet and in good taste for a minister to speak officially of the interests of the great medico-educational institutions of the country as "beggarly vested interests." Of the propriety of such a method of expression, no doubt, the Vice-President of the Privy Council ought to be the best judge, but—to our untutored mind—the phrase is coarse, even if it were truthfully descriptive, and we should have supposed that the right hon. gentleman would consult his own dignity and more effectually proceed to his object by the use of a more courteous address and a less expressive form of speech.

In our opinion these "beggarly vested interests" are in the aggregate entirely worthy of consideration as against the vested interests—not less beggarly—of *soi-disant* Universities who tout for the patronage of medical students by the sale of M.D.'s to simple licentiates.

We do not apply this phrase specially to Scotch Universities, but to all institutions who vend the Doctorate in Medicine to students who are their simple examinees, and in no real sense their academic *alumni*. Whether institutions which engage in this trade are in any degree privileged to override the "beggarly vested interests" of other institutions of not less educational merit, but which do not call themselves Universities, is, we are strongly of opinion, worthy of the consideration of the House of Commons, if not of Mr. Mundella.

At any rate, the attitude adopted by that minister since the Bill passed from Lord Carlingford's hands into his has been clearly calculated to imperil its chances of passing, and, being earnestly anxious that, subject to reasonable amendments, the measure should become law, we are greatly discouraged by Mr. Mundella's inelegancies of diction.

◆

INDIAN MEDICAL SERVICE.

The points at issue between the Indian Government and the Indian Medical Service are of so simple and so practical a nature that it is truly lamentable to see our historic and valuable department drifting into a state of passive resistance and discontent in consequence of the unreasonable obstinacy of those in authority in refusing to submit the causes of complaint to the decision of a Royal Commission, or some other independent tribunal by the verdict of which both parties would be content to abide.

The first grievance put forward by the Indian medical officers amounts in a few words to this:—"that their services have been obtained by the Indian Government under false pretences," inasmuch as the conditions of employment and remuneration implied by the rules furnished to young surgeons seeking the appointments are not subsequently fulfilled, that while the letter of the regulations is in a way adhered to, the meaning which it would suggest to ninety-nine men out of a hundred is set aside for an interpretation which results in a considerable loss of pay to the medical officers, and would have required some legal cunning to have detected.

The paragraph in dispute is as follows:—"A medical officer will, however employed, be restricted to the rate of pay laid down in par. 16 (*i.e.* Rs. 286 *per mensem*) until he shall have passed the examination in Hindustan." The obvious inference from this is that, having qualified by passing this examination, the medical officer will receive the next higher rate of pay; and this is further suggested by another paragraph (18) of the same Memorandum, which specifies that "a surgeon under five years' service, in charge of a native regiment, shall receive Rs. 450 *per mensem*; if over five years' service, Rs. 600." No hint is here given of the existence of such delusions as "unemployed pay" or "officiating pay," and it would in truth require a bold official to put in print the subterfuges of such devices.

The plain facts are these—that medical officers who have passed the required test in Hindustani within six months of their landing in the country find themselves for three or four years subsequently in receipt of the same punishment pittance that was held over them as a threat in case they should delay, or fail to pass in the language; and if not actually in charge of a native regiment, they, even though serving amid the dangers of war or the trying duties of a cholera camp, are with cruel irony told that, according to the letter of the regulations, they are "unemployed," and can only receive "unemployed pay"—viz., Rs. 286 per month.

That the contrast between employers and employed in so important a service should be couched in such ambiguous terms is, to say the least of it, most unfortunate, and we can only suppose that these regulations were framed when, under conditions that have now passed away, the rapidity of drafting medical officers as soon as qualified to civil and military charges was such that the interval between passing the necessary examination and reaching the higher rate of pay was so short as to render its occurrence of no practical moment.

Under the existing state of things, the only honourable course for the Indian Government is to inform intending candidates in a revised prospectus that the increase from the first rate of pay (Rs. 286 per month) will only be given on a medical officer obtaining a civil or military charge, and that this is unlikely to occur before the completion of four years; that such charge, if held temporarily in the absence of the original possessor, will carry but half the increase of pay; and that to reach such beneficial appointment the medical officer may have to proceed from Calcutta to Peshawur at his own expense, and then entering the medical labour market with this programme, to ascertain whether young surgeons of the same stamp and education will continue to compete for the appointments in India. If so, it would be unfair to the country to saddle it with any increased outlay; if not, it would be still more unfair to the Indian Army and Indian community to leave matters in their present condition.

Should this straightforward course not be adopted by the authorities, it will behove the "grinders" and those who in introductory lectures sketch the various careers open to young surgeons to state unhesitatingly the meaning which is found to attach to the loosely-worded paragraphs of the Indian Medical Prospectus which have given rise to the present dissatisfaction.

◆

We regret to learn that Sir George Owens, of Dublin, met with a severe injury to his shoulder by a fall. He is progressing favourably.

Notes on Current Topics.

The Cholera.

Public interest on the dread epidemic raging in Egypt is little less keenly excited at present than at the commencement of the outbreak; but there is not the same "scared" feeling, or at any rate the same extent of feeling, as was evidenced at first among ordinary newspaper gossips and their readers. A certain amount of intelligent inquiry is, however, manifested concerning the disease in many quarters that are not strictly medical, and in consequence of this, information that had not hitherto been gathered in relation to it is gradually being accumulated. One of the most curious observations in this connection is that of a correspondent of *Nature*, who affirms that swallows and sparrows afford certain indications of the approach of cholera to a district, by deserting it in a body; and that the truth of this curious fact has been proved in four former visitations. More important, however, than this is the announcement by M. Pasteur of his belief in the existence of a specific cholera microzyme, of the reality of which he is so convinced that he has strongly recommended the French Government to despatch a commission of inquiry to Egypt, for the purpose of conducting researches into the generation of the disease.

Family Registers.

The great importance which attaches, from a medical point of view, to that portion of a clinical record wherein the family and personal histories of the patient are detailed, is abundantly recognised in all departments of practice; often enough treatment is essentially indicated by the information so obtained, and never can it be said that details of this description are trivial or unworthy of careful collection. By an extension of the method observed by the clinician when dealing with his cases, there might be carried into general adoption by every family in the nation a plan of registration which should include a historical account of the physical being of every member constituting the family, and which in time of sickness might be submitted for guidance of the medical attendant's endeavours. How pricelessly invaluable such a document would frequently be need hardly be insisted on, for the least time-experienced practitioner can readily call to mind instances in which access to a record of the kind would possibly, by directing his earliest treatment of an obscure complaint, have resulted in preserving life that had otherwise baffled his skill to save. The principle involved in such considerations as these is unquestionably admitted by every educated member of the profession; but equally also, the almost unconquerable obstacles in the way of effecting such changes in national manners and customs as shall lead to its universalad option, is fully recognised. Mr. Francis Galton, however, proposes to make the attempt to initiate this necessary reform, by offering prizes to the amount of £500 for registers compiled by medical men and relating to their own families. His scheme is sketched out in the current *Fortnightly Review*, and its details are at least reasonable enough to encourage sanguine hopes of success. Coming from such a source, the proposal will necessarily command respect, for Mr. Galton's researches in heredity have already laid the scientific world under a heavy debt of gratitude to him. That he should rightly appreciate the intimate relations borne to practical medicine by the inquiries he has made the burden of his life, is a very natural consequence of his enlightened studies; and we venture to predict that not only will he find a considerable proportion of the profession prepared to consider his proposal "seriously," but ready in addition to forward the scheme to the fullest possible development. That the subject is one of the very first importance is evident; that the attempt now made to give it special prominence may succeed we sincerely hope.

The Medico-Psychological Association.

The annual meeting of the Medico-Psychological Association was held on July 27th, at the Royal College of Physicians, London, Dr. Orange, of Broadmoor, presiding. After a vote of thanks to Dr. Gardner, the outgoing president, the appointment of officers took place. Dr. Manley was appointed president for the ensuing year. New statistical tables, which had been on trial for a year were adopted, subject to certain revision. At the afternoon meeting Dr. Orange delivered his presidential address on the subject of Criminal Lunatics, and a long and important discussion ensued, in which Dr. Bucknill, Dr. Hack Tuke, Dr. Nugent, and others took part. A resolution was ultimately adopted to the effect that prisoners suspected of being mentally deranged should be examined by competent medical men as soon as possible after the commission of the crime with which they were charged, such examination to be provided by the Treasury, the examiners being the prison medical officer, the county asylum medical officer, and a neighbouring practitioner.

Death under Chloroform.

Another death of a patient while under the influence of chloroform occurred on Thursday last at Whitehaven, in the private practice of Mr. G. Muriel, M.R.C.S. The deceased, a gentleman aged 45, was about to undergo an operation for excision of a tumour from the lip. From the newspaper reports of the inquest it appears that the surgeon was unassisted, and himself administered the anæsthetic prior to commencing the operation. Soon after the inhalation was commenced the patient became livid, and efforts to restore respiration, which quickly ceased, were unavailing. Examination of the body *post mortem* showed that all the organs were in a healthy condition; and a verdict was returned to the effect that "deceased died from sudden paralysis of the nerves, caused by chloroform, which had been properly administered." The jury, however, were sufficiently alive to the peculiar circumstances surrounding the case to suggest that two medical men ought always to be present in similar cases, a reflection which will be shared by every one who rightly appreciates the responsibilities incurred by the administrator of any form of anæsthetic in common use. While expressing sympathy with Mr. Muriel in the misfortune which has befallen him in this instance, it is only right that we should very strongly protest against the unwisdom of which he was guilty in resorting to the employment of chloroform without the assistance of a second professional attendant. The fact, ascertained beforehand, that the patient had been chloroformed on a former occasion, did not justify his being again submitted to the influence of the anæsthetic unless an assistant specially charged with its administration was present also; and it is to be hoped the untoward result in this instance will deter others from running similar risks in the future.

London Hospital Sunday Fund.

The report of the Distribution Committee states that the total amount available for distribution, after allowing sufficiently for liabilities and the usual current expenses, is £32,243, of which they recommend the payment of £29,664 to ninety-seven hospitals, including six institutions which might be classed as hospitals, and £2,579 to fifty-one dispensaries. In addition, 4 per cent. of the total sum collected, amounting to £1,400, was set aside for the purchase of surgical appliances. The institutions participating were three more than last year, and forty-three more than in the first year of the fund.

Medical Titular Distinctions.

Mr. Gibson gave notice for Monday last, to ask the First Lord of the Admiralty, if he could state exactly how many baronetcies are now held by eminent physicians and surgeons in England and Ireland respectively; how many such creations have taken place in England and Ireland respectively within the last five years; and what is the reason for the contrast in the numbers. Col. King-Harman has also put a question as follows:—To ask the First Lord of the Treasury if he has any objection to state whether it is true that he has advised Her Majesty graciously to confer the honour of baronetcy upon two distinguished English gentlemen of great medical and surgical skill; and whether he has also advised Her Majesty to reward the services of an Irish gentleman, who has also attained to great and deserved eminence in the surgical profession, with the simple honour of a knighthood.

A New Antipyretic.

Dr. Fischer, of Munich, announces the discovery of a new medicinal agent, the therapeutic action of which resembles that of quinine, and which he has obtained, by a complicated process, in the form of a white crystalline powder, from coal tar. The name its discoverer has seen fit to give the substance is *Kairin*, and its immediate influence in reducing high body temperatures makes Prof. Fischer sanguine that it will be largely employed for this purpose. It is said to be more readily tolerated than quinine by the human system, but its costly character—nearly ten shillings an ounce—will be for some time a bar to its general employment. It may, however, be made trial of with advantage, and if its virtues correspond with the pretensions put forth in its behalf it must undoubtedly become a valuable addition to the physician's *armamentarium*.

Sir Edwin Saunders, Dental Surgeon to Her Majesty, has just presented a house of the value of £2,400 to the Dental Hospital of London for the enlargement of that Institution.

Emigration for Medical Men.

The cry is so frequently raised that the profession of medicine is overstocked in this country, that any prospect of improved practice to be secured by emigration may be acceptable to a good many young men who are "waiting for something to turn up." In this connection it is interesting to learn that Australia offers advantages which cannot be exceeded at home, if we may judge from the report of a transaction noted in the *Bendigo Independent*, and by which a Dr. Henry L. Atkinson, of Sandhurst, became the possessor of an antipodean estate in consideration of a money payment of £40,000. We are authoritatively informed that the gentleman in question proceeded to Australia some years ago as surgeon on board a sailing vessel, and that the whole of the large fortune he now possesses has been accumulated during his professional career abroad. Such an example may well commend itself to those who are on the look-out for openings here; and while it says much that is highly creditable to the perseverance and industry of the practitioner in question, it also indicates the likelihood that others might fairly hope, with the exercise of similar qualitions, to gain at any rate a competence by the exercise of their profession.

A New Operation for Prolapsus Recti.

From *Il Morgagni* we lear that Dr. D'Antona has performed with success the operation on a woman: Seizing the prolapse with four Billroth's pincettes, and forming thus two cylinders of the rectal canal, he introduced one catgut suture into both cylinders and then into the margin of the anus. Another suture is passed through the middle part of one cylinder, carried through the Douglas sac, and the perirectal tissue, returning to the other cylinder. The patient is discharged, cured in fifteen days.

A Mysterious Case of Poisoning in Aberdeen.

A case, of which the following is a brief account, has been the cause of considerable excitement in Aberdeen for some weeks past. It appears that about the 4th of last January the wife of an iron moulder went to the shop of Mr. Sangster, a druggist, and asked for some salicylate of soda to cure her husband of some slight rheumatic pains from which he was suffering. She was supplied with a drachm and a half of what was supposed to be the drug she wanted. On returning home she divided the powder into six parts and gave her husband one of the divisions. Shortly after taking the powder he went to sleep, and with two or three short intervals of wakefulness he became comatose and died. An investigation was made by the Procurator-Fiscal: the contents of the stomach and the remainder of the powders were examined by Dr. F. Ogston, jun., who reported that the powders were pure salicylate of soda, as evidenced by the violet colour given with a solution of perchloride of iron. On this statement the criminal investigation was dropped. The widow has since, however, commenced an action against the druggist for compensation, laying the damages at £750 for the loss of her husband. On the 21st of March Dr. F. Ogston read a paper before the Aberdeen, Banff, and Kincardine branch of the British Medical Association on the case, describing it as one o poisoning by salicylate of soda. There was considerable discussion. The President, Dr. Angus Fraser, was of opinion that the case was one of poisoning by morphia, and this opinion was concurred in by other members present at the meeting. The case, we learn, has been compromised by the druggist, and, so far as the widow is concerned, we have no comments to make, but we are of opinion that the matter is far too serious to end here. Evidently the salicylate of soda was not pure, for the dose, about 15 grains, was far too small to cause death, especially in the case of a healthy young man of 29 years of age. The preliminary proceedings appear to have been conducted in a very slovenly manner, for surely the fact of a young man in comparative health sleeping his existence away ought to have attracted attention, and led to a more searching inquiry. Such a case could not have occurred in England without a coroner's inquest; and, however faulty that system may at times appear, it seems to us far preferable to the private inquiry method, where a case like the one under discussion is quietly set aside. The case demands a full and careful investigation, and we trust that the Crown authorities will at once use every endeavour to clear up what at present is a most painful mystery and a public scandal.

The Water Supply of London.

The water supply of London, in consequence of the probable visitation of cholera, has become the subject of anxious inquiries in Parliament during the past week. Dr. Cameron succeeded in extracting from the President of the Local Government Board an admission of considerable importance with regard to the scandalous discrepancy of the published results of Dr. Frankland, the official analytical chemist of the Government, and those of the chemists of the water companies of London. We have repeatedly called attention to the fact; for in numberless instances we have noticed a widely important difference, and their misleading nature cannot be considered other than a public scandal, especially when they are allowed to be issued in an authoritative medium, the "Water Examiner's" monthly report made to the Local Government Board, which is printed and published at the public expense. The last report issued in this way differs only in degree from its offensive self-assertiveness and sufficiency; not a particle of submissiveness pervades it, for whilst it claims its own infallibility, it takes occasion to sneer at the official examiner's "moving organisms," and which the chemists of the water companies cannot find, and do not believe would render water less "pure and wholesome" and fit for domestic use. We suppose they would not consider that a large dust contractor's yard immediately adjoining the open filter beds of the Southwark and Vauxhall Water Company, and which was made the subject of complaint by Mr. Egerton, is a matter of the smallest moment, or at all likely to dangerously contaminate the water supply. This disagreeable dust business has been carried on since 1872, and we are told that, although remonstrances have been repeatedly made by the Local Government Board, they have produced no effect upon the Water Company, and are not likely to be regarded, because the Board has no power to compel the company to carry on its business so that it shall not endanger the public health.

The Albert Medal of the Society of Arts has this year been awarded to Sir Joseph D. Hooker.

The death-rates in the large towns from diseases of the zymotic class continue exceptionally low. Even summer diarrhœa has produced but a slightly increased mortality, and it may fairly be said that the country was never in a more healthy state. During the past week only six deaths from small-pox were registered in London, 2 in Birmingham, 2 in Liverpool, and 2 in Newcastle-upon-Tyne, twelve deaths in a population of nearly forty millions being the sum total from this disease.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Birkenhead, 10; Huddersfield, Blackburn, 13; Plymouth 14; Hull, Portsmouth, Bristol, Bradford, Oldham, Derby, Halifax 15; Wolverhampton, Preston 16; Salford, Edinburgh, Norwich 17; Sunderland, Birmingham, Nottingham 18; Cardiff, Sheffield, Brighton 19; London, Dublin, Glasgow, Leicester, Leeds, 21; Bolton 22; Newcastle-on-Tyne 23; Liverpool, Manchester 25.

The *Spectator*, which is usually understood to speak the mind of the Government, writing last week in reference to the recent grant and offer of knighthood in Ireland, enters upon an "odious comparison" between the merits of English recipients of baronetcy and those of possible Irish recipients, and winds up with the observation that "when Dublin men can produce a physician and surgeon who has done as much, we trust they too will receive baronetcies." We shall certainly not follow the *Spectator* into the contrast of professional quality to which it invites us, for we feel that we can well afford to leave to the judgment of the profession the question whether Ireland would have any difficulty in producing representatives of medicine and surgery of scientific and social position at least equal to that held by the gentlemen whom Her Majesty has very properly honoured. The *Spectator* does not indeed set up a standard of merit which it would be very difficult to reach, considering that it describes one of the new baronets as "one of the most considerable practitioners of his day," and the other as deserving of distinction because he succeeded "in persuading middle-aged men and women not to over-eat themselves." We should be very sorry to imagine that Sir Andrew Clark and Sir Prescott Hewett had not some larger claims to baronetcy than those which the *Spectator* considers pre-eminent.

◆

Scotland.

[From our Northern Correspondents.]

The University of Edinburgh Graduation.—The capping of the medical graduates took place last Wednesday, when thirty candidates received the degree of M.D., and one hundred and eighty-three received the degrees of M.B., C.M. The graduation address was delivered by Professor Dickson, in which he took occasion to condemn the Medical Bill now before Parliament, and made some statements not altogether borne out by facts. The chief aim of the Professors of the Scotch Universities appears to be an attack on the English Corporations, which are as a rule vilified in no unmeasured terms. The statements made that the examination of the College of Surgeons is deficient in medicine, and that of the College of Physicians in surgery, could only have been made by one under the impression that charges are more easily made than refuted, and that more people are likely to hear the accusation than the refutation. The facts of the case are these: the College of Surgeons of England requires an examination in medicine or the production of a diploma in medicine. The result of this is that the College of Physicians of Edinburgh reaps an abundant harvest from the above regulation. It is well known that men who have passed the London College come to Edinburgh and undergo an oral examination, and then return for the London diploma. The College of Physicians also examine in surgery, or demand the production of a surgical diploma before granting their licence. The London medical schools were also lectured on their duties, which, according to Professor Dickson, are sadly neglected.

The Scottish Fishery Board and Scientific Investigations.—We understand that, at the request of the Fishery Board, the Lords of the Admiralty have granted the use of a gunboat in order to enable a Committee of the Board, consisting of Professor Cossar Ewart, Sir James R. Gibson Maitland, Bart., Mr. Maxtone Graham, and Sheriff Forbes Irvine, to carry on scientific investigations during the autumn.

Lectureships on Physiology at the Watts Institute.—Mr. James Hunter F.R.C.S.E., after a sharp contest, was elected last week to fill the post left vacant by Dr. Andrew Wilson.

Greenock.—The Broomhill Home for Incurables.—On the 1st inst. a public meeting, composed mostly of ladies, was held in the Temperance Institute—Provost Wilson presiding—to hear Miss Beatrice Clugston. After the Provost had opened the meeting Miss Clugston gave an account of her recent visit to the Royal Hospital for Incurables at Putney and kindred institutions, and made an appeal for the support of the Broomhill Home for Incurables. At the close the following resolution was unanimously agreed to:—"This meeting being fully persuaded that the cause of the incurable must appeal to all classes of the community, and knowing from Miss Clugston's statement that the extension of Bromhill Home can only be made valuable by the directors in proportion to the support given yearly for the maintenance by Glasgow and the West of Scotland, resolves to commend it over the town which this meeting represents, and hereby agrees to form a Ladies' Auxiliary Society to raise, in small sums, a subscription annually worthy of the town, and such as will enable the board of directors to go on with the extension of the valuable work of the Association for the Relief of Incurables."

The Registrar-General's Return.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, July 28, shows that the death-rate was 18·5 per 1000 of estimated population. This is 2·8 below the corresponding week of last year, and also 2·8 below the previous week of the present year. The lowest mortality was recorded in Perth—viz., 8·5 per 1000; and the highest in Greenock—viz., 23·3 per 1000. The mortality from the seven most familiar zymotic diseases was at the rate of 3·2 per 1000, or 1·1 below the rate for the previous week. Diarrhœa and whooping-cough were the most fatal miasmatic diseases. Acute diseases of the chest caused 65 deaths, or 4 less than in the previous week.

UNIVERSITY OF GLASGOW.—The Brunton Memorial Prize, given to the most distinguished graduate in medicine of the year, has been gained by J. Innes Dunlop, M.B., C.M.

EDINBURGH.—HEALTH OF THE CITY.—The mortality in Edinburgh for the week ending with Saturday, the 28th ult., was 70, and the death-rate 16 per 1,000. There were 14 deaths under one year, and 20 above sixty, of which 4 were above eighty and 1 above ninety years. Diseases of the chest accounted for 23 deaths, and zymotic causes for 5, of which 1 was due to scarlatina and 2 to measles—the intimations for these diseases for the week being 25 and 70 respectively.

GLASGOW DEATH-RATE.—The deaths in Glasgow for the week ending with Saturday, the 28th ult., were at the rate of 22 per 1,000 per annum, as compared with 25 in the preceding week, and 25, 19, and 21 in the corresponding weeks of 1882, 1881, and 1880.

ABERDEEN ROYAL INFIRMARY.—At a special meeting of the managers of the Aberdeen Royal Infirmary, held on the 30th ult., to consider the question of filling up the vacancy in the superintendentship caused by the death of Dr. Edward Wagstaff Robertson, a long discussion took place as to whether a medical man should be appointed, or whether the office should, as proposed by the Committee of Management, be thrown open to candidates not having a medical officer's qualification, but having the capacity to administer the general business work of the institution, purchasing of stores, book-keeping, &c. A general opinion was expressed by the managers in favour of appointing a medical man, and in the end a motion was carried to the effect that preference be given to a licensed practitioner, but that the situation should be advertised as open to all candidates. The salary is £250 a year, with a free house and the usual perquisites.

Obituary.

MRS. CHAPLIN AYRTON, M.D., L.K.Q.C.P.I.

WE announce with regret the death of Mrs. Chaplin Ayrton, M.D., a much esteemed and highly gifted member of the profession. Mrs. Ayrton was born at Honfleur, of English parents, in 1846. She was one of the most able of the first Edinburgh class of women students, forming one of the famous "*septem contra Edinem.*" At Surgeons' Hall she especially distinguished herself in anatomy, and the beautiful coloured drawings which she made of all her dissections in their various stages were the admiration of her teachers as well as of her fellow-students. Had her sympathetic nature then had freer scope, the medical woman question in Edinburgh might have been brought to a different termination. When all hope of University recognition was at an end there, and after having passed her first professional examination as an undergraduate of the University of Edinburgh, Mrs. Ayrton left Edinburgh for Paris in 1872; and in the following year she accompanied her husband, Professor Ayrton, to Japan, where she remained until 1877. While there she taught midwifery to a class of Japanese women, having previously herself obtained the Licence of the Obstetrical Society of London. On her return to Europe, Mrs. Ayrton completed the prescribed course of study at the hospitals and medical school of Paris, and then took her degree of M.D. in 1879, her thesis comprising the results of many measurements of the stature and length of a large number of Japanese, with deductions as to the effects on the race of the successive foreign immigrations into Japan, illustrated by lithographs drawn on the stone by herself. She subsequently obtained the Licentiate in Medicine and in Midwifery of the Irish College of Physicians; and after some further clinical study was preparing to establish herself in practice in London, when her health, which the vicissitudes in the long, wearying struggles of her student life had severely tried, broke down, and the remaining three winters were spent in a vain fight with disease on Mediterranean shores. Mrs. Ayrton died of phthisis on July 19, at the early age of 37, leaving behind her one child, a daughter. During her short life Mrs. Ayrton contributed many articles to medical and other papers, and was the author of a well-known work, illustrated by herself, called "Child Life in Japan." We understand that she leaves, ready drawn on the wood by herself, all the illustrations, as well as the manuscript, for a further work on Japanese life.

◆

Medico-Parliamentary.

HOUSE OF COMMONS.—THURSDAY, AUGUST 2ND.

VACCINATION IN WORKHOUSES.

Mr. G. RUSSELL, in reply to Mr. Hopwood, said the guardians of St. Pancras had applied to the Local Government Board for advice as to the propriety of vaccinating women within a few hours after child-birth. The Board had referred the guardians to a circular of Jan, 27, 1881, and to a letter of June last to Dr. Dunlop, in which the Board suggested that the medidal officers should fully consider whether it was desirable that women should be vaccinated or revaccinated shortly after childbirth.

THE CHOLERA AT HOME.

Mr. TREVELYAN, in reply to Colonel Nolan, said that the question of providing temporary hospitals in this country in the event of a cholera outbreak rested with the different sanitary authorities, and not with the Local Government Board. The Local Government Board had no power to secure hospitals or obtain sites for the purpose, but the sanitary authorities had the subject at present before them, owing to a circular which had been sent to them by the Local Government Board.

With respect to infection by the importation of rags, rugs, and carpets, instructions had been given that all rags should undergo disinfection at the various ports before landing; but with carpets and other manufactured goods, this was not necessary.

CRIMINAL LUNATICS.

Mr. R. PAGET asked the Secretary of State for the Home Department if he would be good enough to state to the House what steps, if any, had been taken by the Treasury or other Department of Her Majesty's Government to give effect to the various recommendations contained in the report of the Departmental Commission of the Home Office on criminal lunatics, which was presented to Parliament on the 9th of November, 1882.

Sir W. HARCOURT said that a recent decision of the House of Lords had practically declared the liability to pay substantially in the cases which were recommended by the Commission, and he hoped that an early opportunity would arrive of dealing with the points which were not affected by that decision.

FRIDAY, AUGUST 3RD.

THE CONTAGIOUS DISEASES ACT.

Mr. HOPWOOD asked the Secretary of State for War what was the comparative strength of the military and marine forces at Plymouth and Devonport in the ten weeks of last year and the same period of this year; was the difference in number sufficient to account for an increase of the number of patients in the naval and military hospitals at Stoke and Stonehouse; and did the increase apply to contagious diseases only, or disease generally.

The Marquess of HARTINGTON—It is not very easy for us to fix the naval population on which the hospital ratio has been formed, becauses it fluctuates from day to day by the arrival and departure of vessels. With regard to the military force, the admissions to hospital of cases of contagious disease during the ten weeks ended July 20 of this year were 183, on a total force of 2,859. The number for the corresponding ten weeks of last year was 116, on a total force of 2,457. With reference to the Navy, the returns have not been procurable week by week, but on the 21st of July, 1883, there were 121 cases of contagious disease in hospital, on a total force of 7,309, while on the corresponding day of 1882, the number of patients was 47, on a total force of 7,324. The total admissions into hospital during the ten weeks of the present year were larger than during the same period in 1882, the number arriving being then 312, against 460 this year, and cases of contagious disease counting for 67 out of a total increase of 148. The total number in hospital with regard to the Navy was 263 last year, as against 377 this, the increase of cases of venereal disease being 74 out of a total increase of 94.

◆

THE EGYPTIAN CHOLERA CONTINGENT.

The deliberate exclusion of Irish medical practitioners from a place in the medical contingent sent to Egypt to combat the cholera epidemic was very properly and judiciously taken in hand last week by Dr. Lyons, M.P. The following gentlemen formed the first batch, specially appointed :—Drs. Theodore Acland and Gulliver, of St. Thomas's Hospital; Dr. J. G. Thrupp, of St. George's Hospital; Drs. S. Wyborn, F. E. Taylor, and A. Honman, of Charing Cross Hospital; Dr. H. Crookshank, of University College; Dr. James Cantlie, of Aberdeen University; Dr. A. F. Wilkins, of Edinburgh University; Dr. M'Nalty, of the Army Medical Department; Dr. Armand Leslie, of the Middlesex Hospital; and Dr. C. F. Porter, of Manchester. Immediately on learning that these appointments had been made, Dr. Lyons, on the suggestion of the President of the Irish College of Physicians, telegraphed to Lord Edward Fitzmaurice, at the Foreign Office, expressing great disappointment that no Irish doctors were selected for Egypt, though English and Scottish schools were represented. In his reply, Lord Edward Fitzmaurice stated that all appointments "were made on the recommendation of Sir Joseph Fayrer, but that only two Irish doctors applied, one of whom was appointed, and the other selected, but afterwards declined. After the number was completed, two candidates from Belfast applied, and their applications will be borne in mind should any further doctors be required."

In a subsequent letter Dr. Lyons was further informed that, as time pressed, Lord Granville had directed the selection to be made on the recommendation of Sir Joseph Fayrer, which was done. Lord Edward Fitzmaurice further states that preference was given to those who had had experience of cholera, and as regards the question of nationality or place of education, he states that Dr. Crookshank, Dr. McNalty, and Dr. Porter all held Irish licences. Notwithstanding this attempt at explanation, Dr. Lyons proceeded to London and asked in the House the following question : "Whether, should unhappily further medical aid be required to meet the cholera visitation in Egypt, he will afford to the Irish Medical Schools and Colleges an opportunity of sending a contingent to share in the honour of this important and distinguished service, and to ask the noble lord why such a step was not in the first instance taken." The action of Dr. Lyons in this matter was entirely justified by the circumstances, and the reply of Lord Fitzmaurice to his complaint was entirely unsatisfactory. It does not, in our opinion, at all mend the matter that Sir Joseph Fayrer should have been the agent of the Foreign Office in this one-sided selection, nor is the suggestion which Lord Edward Fitzmaurice puts forward in defence at all worthy of consideration. Two classes of men were selected by Sir Joseph Fayrer—experienced army medical officers who had seen cholera and juniors who could act under their direction. Amongst the former class there happened to be three gentlemen who twenty years ago or thereabouts took Irish degrees. Amongst the latter class not a single Irishman or Irish-educated Englishman was allowed a place, nor was any opportunity afforded to Irish surgeons to send in their names. The appointments were made without any public notice whatever, and it would have been quite easy for Sir Joseph Fayrer and the Government to have avoided the appearance of partiality by sending a telegram to each of the Irish and Scotch colleges asking them to recommend a couple of men. This transaction coming after the exclusion of Irish candidates from the Army Medical Department, which we exposed some months ago, and with which proceeding Sir John Fayrer was indirectly associated, is certainly not calculated to remove the suspicion that the authorities are not free from partiality and prejudice, or likely to do what is fair toward the profession in Ireland.

◆

THE IRISH POOR-LAW SUPERANNUATION BILL.

We announce with much satisfaction the second reading of this Bill, which has been for two years before Parliament. Having been introduced by Mr. Herbert Gladstone on behalf of the Government, and at the instance of the Irish Medical Association and Poor-law Officers' Association, it was last year sent to a Select Committee, where its details were examined into and an understanding arrived at which, it was hoped, would satisfy almost all parties. This year the Bill has been delayed until this late period by the opposition of Mr. Biggar, who goes for the principle that Guardians are entitled to the God-like prerogative to "larrup their own niggers," and that therefore the proposal to restrict their right to taking all they can get out of an officer and leaving him to starve afterwards ought not to be tolerated. He moved the rejection of the Bill, and was ably answered by Mr. Meldon. Upon the passing of the second reading the Irish party were divided between those who rejected it altogether and those who approved its principle but objected to details. The neck-or-nothing opponents were Messrs. Biggar, O'Kelly, Dawson, O'Brien, Leamy, and Lalor. The tolerants were Messrs Healy, W. H. O'Sullivan, and Parnell. The supporters were Mr. H. Gladstone, Mr. Meldon, Colonel Tottenham, Colonel King-Harman, and Mr. Corry. The second reading passed by 80 votes to 25.

It seems likely that further amendments will be sought for at the committee stage. It is for instance proposed that at least half the pension should come out of the Consolidated Fund, as half salaries do now. It is also proposed that a minimum pension should be fixed below which no board of guardians should go, but that a discretion should be allowed them to go as much above the minimum as they pleased within reasonable limits. This proposition would, if carried into effect, greatly mar the Bill, for we know that many unions—for example, those of Cavan, Wexford, and Belfast —would never grant a penny over the minimum, and thus length of service would be no advantage to the applicant. The date of the committee stage of the Bill is not yet fixed, but it must be soon, and we shall inform our readers thereupon.

University of Glasgow.—The following is a list of degrees conferred in the Faculty of Medicine at the graduation ceremony on Thursday, July 26th :—

Doctors of Medicine (M.D.)

Allan, G. R., M.B., England.
Campbell, A., M.B., Scotland.
Caskie, W. A., M.B., Scotland.
Couper, D., M.B., Scotland.
Denholm, A., M.B., Scotland.
Highet, John, M.B., Scotland.
Howie, Thomas, M.B., Scotland.
* Inglis, D. W., M.B., Scotland
* Newman, D., M.B , Scotland
Ochiltree, E. G., M.B., Australia
Prichard, Richard, M.B., Wales
Stewart, C. W., M.B., Scotland
Wilson, J. M., M.B., Scotland
Yair, John M., M.B., Scotland

* Commended for Thesis.

Bachelors of Medicine and Masters in Surgery (M.B. & C.M.).

Adam, William T., Scotland
Aitken, Wm. B., Scotland
Alexander, Samuel, Ireland
Alexander, Thos. G., Scotland
Arthur, David, Scotland
Beveridge, Robert E., Scotland
Binnie, Robert M'G., Scotland

Notices to Correspondents.

DISPENSER.—The Pharmaceutical Society of Great Britain controls the examinations and curriculum. You had better make an application to the Secretary for information.

IN reply to "Verneuil," we are sorry to inform him that all appointments to Militia regiments have been done away with, the duties being now performed by the Army Medical Department, or by civilians at contract rates. To obtain an appointment as surgeon to a Volunteer corps, interest must be made with the officer commanding the corps, and the appointment ratified by the War Office.

THE EXHIBITS AT THE LIVERPOOL MEETING.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your last issue your special correspondent, in his article on the meeting of the British Medical Association at Liverpool, writes: "The stall of Newbery & Sons contains some well-made emulsions of cod-liver oil." To prevent misconception, permit us to point out that the emulsion exhibited is manufactured by Messrs. Scott & Bowne, of New York, for whom we are agents, and is known to the profession as "*Scott's* Emulsion of Pure Cod-liver Oil with Hypophosphites of Lime and Soda." Yours &c.,

London, August 3. F. NEWBERY & SONS.

DR. W. O. will please receive our best thanks; we shall be glad to hear further from him.

DE REBUS.—We regret our inability to oblige you. The subject has already been exhaustively discussed.

MR. MORTIMER.—Hazeline is a very valuable preparation, which has stood the test of extended trial, and may be employed with absolute reliance on its good properties.

PILLMAKER.—Consult either Proctor's "Lectures on Practical Pharmacy," or Whitla's "Materia Medica, Pharmacy, and Therapeutics."

DR. THORNLEY.—We shall be glad to have the reports.

A PUZZLED CANDIDATE.—Your experience is by no means unique, but you may probably be enabled to understand the occurrence more easily by asking for an explanation from the examiners, who, if courteously addressed, will no doubt give you some valuable information about yourself.

K. L. A.—We cannot tell you "if the Bill will pass." We only know that an effort to pass it has been promised.

MR. WALTERS.—The leading medical periodicals of Berlin and Vienna are the *Deutsche Medizinal Zeitung* and the *Wiener Medizinische Zeitung* respectively. Both are weekly, and can be obtained in this country at the leading foreign publishers' and booksellers'.

DR. GARRARD.—Our attention has been called to the journal in question on a previous occasion. Upon inquiries we found that it was the property of a notorious quack, who places his name side by side with the leaders of the profession, so as to appear in good company before his victimised readers. As exposure would have been of service to him, we refrained from giving him the advertisement, and we think it wise to follow the same course on the present occasion.

CHEMICUS.—Chloral was discovered by the late Baron Liebig, who obtained it by submitting absolute alcohol to the action of chlorine gas. The name chloral was derived by a union of the first syllables of the two sources of its origin—Chlor (ine) al (cohol).

MR. ARKWRIGHT.—Your request is a most unusual one, and cannot be complied with unless the free consent of the writer is first obtained. Even then we should prefer not to make the statement.

O. H—The cost is very trifling.

◆

Vacancies.

Aberdeen Royal Infirmary.—Superintendent. Salary, £250, with residence. Full particulars on application to the Treasurer.

General Infirmary, Gloucester.—House Surgeon. Salary, £100, with board. Applications to the Secretary before September 1.

Gloucester County Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to the Medical Superintendent at Wotton, on or before August 20.

London Hospital.—Demonstrator of Practical Chemistry. Salary, £100, and a proportion of fees. Applications to the Warden before September 1.

North Wales Co. Lunatic Asylum, Denbigh.—Assistant Medical Officer. Salary commencing at £100, with board. Applications before August 16. (See Advt.)

Sheffield Union.—Medical Officer for the Central District. Salary, £60, with the usual extra fees. Applications to the Clerk to the Guardians on or before August 13.

Ulverstone Union.—Medical Officer of Health for the Rural Sanitary Authority. Salary, £133. Sealed applications to the Clerk before August 22nd. (See Advt.)

Worksop Dispensary.—House Surgeon. Salary, £120, with furnished apartments and extras. Applications to the Hon. Sec.

Appointments.

BENNETT, Mr. F., House Surgeon to the Manchester Royal Infirmary.

CREAGH, W., M.D. Dub., L.R.C.S.I., Medical Officer for the Rolleston District, Burton-on-Trent Union; and to the Clifton District, Tamworth Union.

DEVONALD, A., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Llannon District of the Llanelly Union.

EVANS, Mr. W. A., House Physician to the Manchester Royal Infirmary.

GIBB, W., M.B., C.M., Assistant Physician to Woodilee Asylum, Lenzie.

HOSEGOOD, W., M.B., M.S. Ed., Medical Officer of Health to the Amersham Rural Sanitary Authority.

HUGHES, T. J., M.R.C.S., Medical Officer for the First District and Workhouse of the Church Stretton Union.

JONES, Mr. J. H., House Physician to the Manchester Royal Infirmary.

MILLS, Mr. W., House Surgeon to the Manchester Royal Infirmary.

SKRIMSHIRE, C. P., M.R.C.S., Public Vaccinator for the Brynmawr District of the Crickhowell Union.

SMITH, J., M.R.C.S., S.Sc.C. Camb., Medical Superintendent to the Dalrymple Home for Inebriates.

VERDON, W., M.D., F.R.C.S. Eng., Medical Officer of Health for Lambeth.

WALKER, H., M.D. Ed , M.R.C.S., Medical Officer for the Kingswinford District of the Stourbridge Union.

Deaths.

BRADFORD.—July 28, at San Francisco (while on sick leave from Hong Kong), Henry Bradford, Surgeon-Major A.M.D., fourth son of the late Rev. John Bradford, Vicar of Pinhoe, Exeter, aged 33.

LEWIS.—July 30, at El Warden, near Cairo, of cholera, Charles Blake Lewis, L.R.C.P. Ed., M.R.C.S., A.M.D., eldest son of the late Charles Warner Lewis, Barrister-at-Law, aged 29.

MCCLELLAND.—July 31, at St. Leonards-on-Sea, John McClelland, M.D., late Inspector-General of H.M. Indian Forces.

MEASE.—July 27, suddenly, at Cavan, Andrew Mease, M.B. Dub., L.R.C.S.

PURDON.—July 31, at his residence, Curristown, Killucan, Charles Purdon, M.D., J.P.

ROYAL COLLEGE of PHYSICIANS of LONDON.

BRADSHAWE LECTURE, August 18th, at 4 o'clock.—Dr. J. Wickham Legg. "Cardiac Aneurysms."

Any Gentleman of the Medical Profession will be admitted on presenting his card.

(By Order of the President)
WILLIAM GURNER,
Bedell.

ROYAL (DICK'S) VETERINARY COLLEGE,
CLYDE STREET, EDINBURGH.
(*Founded by the late Professor Dick*, 1823.)
Trustees—LORD PROVOST, MAGISTRATES, AND COUNCIL OF THE CITY OF EDINBURGH.
Principal—Professor THOMAS WALLEY, M.R.C.V.S.
WINTER SESSION commences 24th OCTOBER.
Prospectuses and full particulars on application.
CLASSES open to Amateurs.

The Medical Press and Circular.

FURTHER OBSERVATIONS ON CERTAIN CEREBRO-NERVOUS DISEASES PECULIAR TO WOMEN. (a)

By THOS. MORE MADDEN, M.D., F.R.C.S.E.,

Obstetric Physician, Mater Misericordiæ Hospital; Physician, Hospital for Children, Dublin, &c.

WITHIN the comparatively short period covered by the annual reports of the Commissioners in Lunacy the number of persons registered as insane in Great Britain has become more than doubled, the proportion of lunatics having increased from one in 800 to one in 300 of the population. Moreover, whereas formerly there was a larger proportion of male than of female lunatics in this country, now there are more insane women than men under restraint in our lunatic asylums. A similar observation may be made with regard to the protean forms of nervous disorders which are so prevalent amongst women.

The explanation of the increasing tendency to cerebro-nervous affections observable in women lies, according to Dr. More Madden, in the greater prevalence of those utero-ovarian complaints which have come into such prominence during the past twenty years, and which, the author holds, are in many cases productive of sympathetic and reflex cerebro-nervous irritation and functional derangements.

The subject has not attracted in this country anything like the attention paid to it by American authorities, and which, from its social as well as professional importance, it demands. Hence, having recently brought some aspects of this question before the Irish Academy of Medicine, the writer now submits to the judgment of the British Medical Association a few observations on certain generally ignored points of interest with reference to the connection between utero-ovarian disorders and the most common forms of cerebro-nervous disease.

The predominant influence of the female reproductive organisation is manifest in every vital action, in health and disease, from the approach of puberty until the menopause has passed. During this long period, at every monthly catamenial epoch, a certain amount of constitutional and nervous disturbance is always present. When menstruation has become established, and is normal in every respect, this disturbance may be so slight as to escape observation. But the earlier catamenial periods and every subsequent deviation from healthy menstruation, as well as the menopause, are almost invariably attended by some manifestation of hysteria.

In the gynæcological wards and extern department of the Mater Misericordiæ Hospital, Dublin, during the last five years, some 2,500 patients have come under Dr. More Madden's observation, and in thirty per cent. marked symptoms of reflex nervous irritation or disorder, traceable to utero-ovarian causes, were noted.

Amongst these cases were seventeen instances of *hystero-epilepsy*, the writer's experience of which was not in accord with that of Dr. Graily Hewitt as to the pathological importance of uterine displacements or flexions in such cases, as in only four of them was there any displacement, whilst in most instances there was accompanying menstrual disorder, and in every case without exception there was some form or other of derangement of the female sexual health.

Hysterical trance had in several cases come under the writer's observation. In one instance the patient thus affected remained in a lethargic condition hardly distinguishable from death for nine days. In another the hysterical trance lasted for one hundred and forty hours. Both patients, whose cases are detailed in the paper, recovered.

Hysterical paralysis, traceable to neglected utero-ovarian functional disturbance, is dwelt on at some length, and illustrated by cases.

Hysterical insanity is, perhaps, the most important and the most neglected of all the remote consequences of unsuspected disease of the female sexual organisation. The mental affections generally associated with chronic uterine or peri-uterine diseases, and with menstrual derangements are, in this incipient stage at least, usually characterised by exaggerated nervous susceptibility, intense egoism, extreme irritability of mind or temper, and perversion of the moral faculties, the abnormal condition of which are often apparent long before any tangible delusions can be recognised. But, although in such cases only the moral faculties may be seemingly affected, it will always be found that some derangement of the intellectual powers, however obscure, co-exists, and even if not evidenced at the time, is certain sooner or later to follow the moral insanity which in hysterical women is apparently the primary mental disorder consequent on reflex utero-ovarian irritation or disease. In many cases its evident connection between menstrual disorders and the causation of mental disturbances has been admitted even by alienists. The influence of puerperal septicæmia on the production of puerperal mania is another illustration of the connection between uterine and cerebral disease. The writer refers at some length to cases of insanity apparently originating from reflex irritation occasioned by utero-ovarian disease, in which the patients were restored to mental as well as physical health by the ultimate recognition and cure of the local disorder. In one case a lady was thus enabled to resume her place in society after many years' seclusion in an asylum where she had been regarded as an incurable lunatic. And Dr. More Madden argues that amongst the fifty thousand women now under restraint in the lunatic asylums of the United Kingdom there are many cases in which the patients are merely suffering from reflex mental disturbances, which would probably subside as soon as its physical exerting cause was removed.

(a) Abstract of a paper read before the British Medical Association.

Most alienists pay little, if any, attention to gynæcology. Most insane patients display a peculiar insensibility to the physical consequences of their intercurrent diseases. Hence, although no uterine examination, and more especially in an insane patient, should ever be made without absolute necessity, the proofs of that necessity are not, under these circumstances, likely to be recognised. Therefore, in any future legislation on insanity provision should be made that independent and specially skilled medical advice should be made available to the inmates of every female lunatic asylum.

Besides the local diseases and functional disturbances of the sexual system referred to, there are other causes of the tendency to cerebro-nervous disorders now so prevalent in women. These causes include amongst others —1. The premature and undue stimulation of the sexual functions. 2. The increasing prevalence of alcoholism in both sexes and in all classes of modern society. And, 3. The grossly misdirected or neglected moral and mental training of a large proportion of female youth. The results of these causes are daily met with in gynæcological practice, and are not only seen in the diseases of the sexual system which come under our special care, but are still more traceable in the mental and moral deterioration, the prevailing nervous hyperæsthetic condition and want of physical training as well as of healthy moral tone which are now too noticeable among women. Moreover, women are no longer, as was formerly the case, to a large extent exempt from those predisposing causes of utero-nervous disorders which in men are recognised as amongst their most common sources. Now-a-days, on the contrary, women are not only liable to those special causes of nervous disorder which arise from utero ovarian irritation, but they also too frequently, as Dr. More Madden has before observed, voluntarily expose themselves to all the incidental causes of insanity to which men were formerly liable. An increasing tendency to insanity and nervous disorders of every form is one result of that hopeless contest with Nature's laws in which those are engaged who seek to unsex themselves by assuming all masculine pursuits and modes of life, which may be too dearly purchased at such a cost.

WIESEN AS A HEALTH RESORT IN EARLY PHTHISIS, WITH DIRECTIONS FOR CLOTHING, DIET, AND EXERCISE IN THE SWISS ALPS DURING WINTER. (a)

By A. T. TUCKER WISE, M.D.,

Formerly Visiting Physician to the Infirmary for Consumption, Margaret Street, Cavendish Square.

Introduction.

The first impression on beholding a snow-clad landscape in a cold climate during fine weather is one of surprise and admiration. Conscious of excessive cold by external appearances rather than by disagreeable sensations of chilliness, one almost doubts the reality of the low temperature. A bright sun and blue sky overhead, a clear and quiet atmosphere, distant sounds transmitted to the ear through the still air, combine with the charms of the scenery to produce such buoyancy of spirits that a man is braced and invigorated for almost any exertion.

An Englishman inured to a damp and windy climate, and with an inherent love for outdoor sports and exercise, feels new life and energy as he views the glassy expanse of a frozen Canadian lake surrounded by dense forest, or makes his way through the rugged boulders and pines of Nova Scotia. A blazing sun above would almost persuade him it was summer, whilst he recognises the sing-song of the sleigh-bells in the distance, miles away it may be, and tastes the keen atmosphere of a bright winter's day.

There may be several degrees of frost, but there is seldom that piercing, raw cold experienced in England, which depends mainly on the quantity of moisture in the air and the force of the wind rather than on the pitch of the thermometer.

The effects on the Anglo-Saxon race of living in a cold climate may be seen in Canada and some of the Northern States of America, where the race is physically superior and more vigorous than that of the parent stock. This, no doubt, depends to a large extent on the mode of life, quality of food, and outdoor exercise taken, in addition to an artificial selection of species in emigration. Nevertheless, such is the fact that these cold climates, with wide ranges of temperatures, harden the European constitution by invigorating the whole frame, and rendering the body less susceptible to changes in temperature, privation, or disease.

What the eventual results will be on the English race by the growth of population and consequent increase of indoor employment, it is difficult to foretell. Certain it is that dwellers in large towns, *employées* in factories, workshops, warehouses, offices, &c., are not exposed to the most favourable conditions of life in regard to health and robust development; and although the "survival of the fittest" will select the strongest and most suitable being to withstand what may almost be termed the ravages of civilisation, even the selected one will scarcely be improved by the deteriorating effects of over-crowding, impure air, improper food want of sunlight, and equable exercise of all the organs of the body.

With examples before us of the health-giving properties of cold regions, it may seem an oversight that cold climates as "change" never received the attention they merited until within recent years.

One of the first to foreshadow the track which is now being pursued by many of the leaders of medicine in England, France, and Germany was Dr. Bodington, a practitioner in Warwickshire, who recommended "dry, frosty air" in the treatment of pulmonary consumption. In a small *brochure*, published by him forty-three years ago on this subject, he said: "To live in and breathe freely the open air, without being deterred by the wind or weather, is one important and essential remedy in arresting its progress—one about which there appears to have generally prevailed a groundless alarm lest the consumptive patient should take cold. . . . . The abode of the patient should be in an airy house in the country—if on an eminence, the better. The neighbourhood chosen should be dry and high; the soil generally of a light loam, a sandy, or gravelly bottom. The atmosphere is in such situations comparatively free from fogs and dampness. The patient ought never to be deterred by the state of the weather from exercise in the open air; if wet and rainy, a covered vehicle should be employed, with open windows. The cold is never too severe for the consumptive patient in this climate. The cooler the air which passes into the lungs, the greater will be the benefit the patient will derive. Sharp, frosty days in the winter season are most favourable. The application of cold, pure air to the interior surface of the lungs is the most powerful sedative that can be applied, and does more to promote the healing and closing of cavities and ulcers of the lungs than any other means that can be employed. . . . . Many persons are alarmed and deterred from taking much exercise in the open air from the circumstance of their coughing much on their first emerging from the warm room of a house, but this shows that the air of the room was too warm, not that the common atmosphere was too cold." As adjuncts, he advocated the use of milk, wine, and generous diet. (*a*) In these remarkable sentences are clearly signalised the indications for residence at such health resorts as the high Swiss Valleys, and they anticipate in an unmistakable manner the treatment of pulmonary disease or weakness by what is now termed, somewhat euphoniously, the "high altitude cure."

(a) Read at the meeting of the British Medical Association at Liverpool, August, 1883.

This English practitioner appears to have been the first, or among the first, to introduce to notice as a therapeutic agent "dry, frosty air," which has proved itself to be a remedy of practical value and application in the treatment of disease.

In more recent years Dr. Herman Weber, with eventual success, drew attention to high, cold altitudes as presenting favourable conditions during winter months for the arrest or amelioration of phthisis. To him undoubtedly belongs the credit of having brought the subject prominently before the profession in a clear and intelligible manner, with results on patients who had wintered in the mountains. For about six years Davos Platz has attracted large numbers of *poitrinaires*, and from reports published by English physicians at home the efficiency of mountain air in some cases of phthisis is undeniable. (*b*)

As may be expected, there are numerous sheltered spots in Switzerland where health may be sought with advantage, and where the benefits of living amongst a scanty population at a high altitude are associated with clean air and sunlight.

St. Moritz possesses the climatic characteristic of an Alpine health resort in having cold, dry, calm days, with plenty of sun. It is situated 1,000 feet higher than Davos, with grander and more picturesque scenery, and the principal hotel has the advantage of being placed about 300 feet above the floor of the valley. Although the past winter was exceptionally bad, as it was everywhere in Europe, the clear, bright, and invigorating days were quite similar to those of Davos, and delicate patients were enabled to sit out of doors in the sun without any danger of chill or sensation of cold. The results on patients who wintered there were pronounced by Dr. Holland to be eminently satisfactory, in spite of the adverse circumstances; whilst, on the other hand, the "cures" at Davos Platz were by no means so gratifying as during previous seasons. The Engadine was recommended some years ago as a winter station for chest complaints. Dr. Burney Yeo represented the advantages of its cold and dry climate, but at that period the high lands in Switzerland were not appreciated as they are now, and the experiment of sending patients there failed through a misunderstanding of the requirements of such cases. Now, however, the principal hotel offers every ordinary comfort to those who winter at St. Moritz. Two ice rinks are in constant use, and numerous tracks are kept in good order for tobogging. Another place which deserves special mention is Andermatt, situated in the Urseren Valley, and well sheltered from wind. It has the inestimable convenience of being only 28 hours from London, with a short drive of less than an hour on arriving at Göschenen. As this latter place is on the St. Gothard line, visitors can move on to the Riviera in a few hours if the mountain air is found unsuitable. A first-rate hotel—the Bellevue—is prepared to receive winter guests, and there is no doubt that this central and easily-approached locality will, when better known, prove attractive to many who wish to spend a few months in the Alps during winter. In the near future, however, the Belgian project of building a Kurhaus, with mechanical arrangements for the propulsion of cleaned, moistened, and warmed air into the interior of the building, will undoubtedly meet with success in a sanitary point of view, and will be the first true attempt to construct an efficient system of ventilation in the "cure" establishments of the Swiss Alps, where people congregate with a view of breathing mountain air, but occasionally inhale the used-up air of the interior of a hotel, flavoured with carbolic acid.

Those who are unacquainted with high altitudes in winter may perhaps be inclined to judge the sensations at a high cold region from an English standard of cold, thinking possibly that twenty degrees of frost signifies twenty degrees of chilliness, and that any temperature below freezing point would be likely to cause discomfort to delicate persons. A brief explanation may tend to correct this view. The body can be deprived of its heat in four different ways:—

1. By conduction, or contact with colder substances, either solid, fluid, or gaseous.
2. By evaporation from the surface of the skin, and the mucous membrane of the respiratory tract.
3. By excretory matters leaving the body; and
4. By radiation.

Now, although it is possible from the hygrometric state of the atmosphere that an additional quantity of moisture is evaporated from the skin and respiratory tract, at high levels, (*a*) this variation plays a very minor part in sensibly reducing the temperature of the body compared to the abstraction of heat by conduction; or, in other words, contact with cold air in movement. This latter cause is the one which principally bears on the question of sensation, inasmuch as cause No. 3 is too insignificant to be felt, and No. 4 can be guarded against to a great extent by clothing.

The physical sensibility of cold is produced by the amount of heat rather suddenly abstracted from the body (which does not always depend on the temperature in contact with it). For example, if the hand be placed on fur at 30° Fahr., it feels warm in comparison with iron at the same temperature. The former being a bad conductor—owing to the *motionless* air in its interstices—does not abstract much heat from the hand ;the metal, being a good conductor of heat, appears intensely cold to the touch.

If, therefore, cold, motionless, dry air surrounds the body, heat is not abstracted nearly so readily as it would be by somewhat warmer air in movement. It must be remembered that the sensation of cold cannot be accurately gauged by reference to the thermometer. Two other conditions are intimately connected with temperature in causing impressions of cold or heat—viz., wind and moisture, for it is these that cool the body, by conduction. If their temperature is lower than ours, they appear colder than they really are, because from their conductivity heat quickly passes away from us.

(*a*) "Essay on the Treatment and Cure of Pulmonary Consumption." By George Bodington. 1840.

(*b*) Dr. Clifford Allbutt, *Lancet*, 1879; Dr. C. Theodore Williams, International Medical Congress Transactions, 1881; Dr. Burney Yeo, "Health Resorts and their Uses;" Dr. Drysdale, *British Medical Journal*, 1882; Dr. Marcet, and others.

(*a*) It must not be supposed that evaporation from the body depends entirely on the percentage of humidity in the air. The conservativ and balancing agencies of physiological action amongst other thing constringe or dilate the cutaneous capillaries in response to cold or heat, rest or exertion, &c.

In the high valleys of the Alps, although the thermometer may register some 15° or 20° of frost, this low temperature is by no means disagreeable, as the calm air and intense solar heat enable many persons to sit in the open and bask in the sun during the depth of winter. Even excessive tanning and reddening of the skin takes place with almost everyone who takes plenty of outdoor exercise: ladies, who are generally well protected by sunshades or umbrellas, do not escape a healthful aspect. This is mostly owing to the reflection of light from the snow, which, coming in upward and parallel directions, cannot be well screened from the face. The habit and necessity of wearing smoked-glass spectacles also enables persons to face the glare, and thereby receive a much larger proportion of light than in England. (*a*)

The physiological action of sunlight and other atmospheric conditions at high altitudes have been discussed in a former publication, (*b*) but a summary here may not be out of place.

The general conditions noted were as follows :—

1. Dryness of the atmosphere, and its comparative freedom from mechanical irritants, germs, and noxious gases (aseptic air).
2. Profusion of sunlight, with a low temperature.
3. Diminished barometric pressure.

The results on pulmonary complaints may be stated thus :—

1. Lessened irritation of the respiratory tract from absence of dust.
2. Evaporation of morbid secretions in the lungs, promoted by reduced barometric pressure and dryness of the atmosphere.
3. Increased oxidation of blood and tissue, from sunlight, cold air, and reduced pressure.
4. Increased quantity of blood circulating in the lungs —caused by the low temperature—the freedom of the circulation being aided by extended chest movements.
5. Increased activity in the pulmonary lymphatics (depending on circulation and expansion), and a general improvement in nutrition; also an exhilarating effect on the nervous system.

Some of these results are obtainable under no other conditions than those presented at high cold regions. With regard to the increased quantity of blood circulating in the lungs (presumably influencing the nutrition of those organs), it may be contended that this is not a desirable sequence. Perhaps it is not in hæmorrhagic phthisis; but in some other forms, especially early tubercular deposits, it would not seem to be disadvantageous. What would lead one to suppose this is the rare occurrence of tubercular phthisis in persons affected with mitral disease. Even when hæmoptysis takes place, and when some of the blood presumably gravitates into the air cells, tubercular disease rarely follows; whilst, on the other hand, phthisis is not an uncommon consequence after hæmoptysis from other causes. This would appear to indicate that a general hyperæmic condition of the lungs impedes the deposition of tubercle and restrains phthisical processes.

Conversely, where the quantity of blood circulating in the lungs is lessened, as in hot climates, phthisis is frequently seen to run a very rapid course.

It is not improbable that this increased volume of blood moving in an impaired and imperfect lung at a high altitude compensates to some extent for its loss in volume, and plays an important part in the nutrition of the tissues and in augmenting the movement of lymph through the pulmonary lymphatics, so removing by absorption many of the smaller morbid cell growths.

On the other hand, the emphysematous signs presented by patients who may be said to be cured, after a prolonged residence at high stations, may seem to contra-indicate any theory based on this assumption. It must be conceded, however, that with the expansion of the chest obtained, it is doubtful if emphysema occasions such compression of the pulmonary capillaries as to decrease the whole volume of blood circulating in the lungs.

That the lungs contain more blood in a cold climate is pretty clear, if we accept the evidence of Dr. Francis (Bengal Army), who found from a large number of observations that the lungs are lighter after death in Europeans in India than the European standard. Parkes confirms this, and also Rattray, in his observations of diminished respiratory function in hot climates.

When the activity of any organ of the body is augmented, more blood is attracted to it than when at rest or during lessened exertion. By breathing rarefied air at high levels the respiratory movements are usually quickened and extended, especially on taking exercise.

The liability, also, of the natives of these high valleys to pneumonia, while exempt from phthisis, would seem to point to some alteration in the vascular condition of the organs affected.

What result any variation in the vascularity of the lungs would have on the bacillus tuberculosis is rather premature to surmise. No bacilli have, however, up to the present time been discovered in the blood of tubercular subjects. It appears, therefore, that either they do not enter the vessels, or, if entering, are changed in character or destroyed. That the state of the blood, chemical or pathological condition, or functional activity of the tissues must be agencies governing the suitability of the soil for the reception of the bacillus is supported by the fact that infection is very rare, although there are numberless cases in which bacilli have undoubtedly been inhaled.

It is well known, also, that the hygrometric and barometric states of the atmosphere modify the process of evaporation from the lungs (*a*) and skin. The evaporation of morbid secretions in the lungs was pointed out in 1881 (*b*) as being one of the conditions which probably has a favourable bearing on phthisis. The process of evaporation in dry climates, acting on ulcers, cavities, or suppurating surfaces, may illustrate by a natural phenomenon the "dry treatment of wounds," so successfully carried out by Mr. Gamgee, of Birmingham.

The effects on the body of sunlight and reduced pressure are doubtless those facilitating the interchange of gases in the blood and tissues, whilst the cold air necessitates the requirement of a larger expenditure of oxygen and assimilation of hydro-carbons to maintain the heat of the body. It may be conjectured that this contributes to the sudden and considerable push given to nutrition on arrival at a cold high altitude, when the appetite is, in most cases, at once improved in a remarkable way, and animal food that could hardly be thought of in England

---

(*a*) It has been frequently noticed that dark-complexioned individuals become sunburnt more readily than "blondes." This depends principally on the sensitiveness of the retina and the colour of the eyes. For instance, "fair" people cannot face the light with such ease and comfort as those who have plenty of pigment in their ires; for the pigment absorbing the rays of light, protects the retina, and even enables some with very "dark" eyes to gaze on the sun itself. On the other hand, a person with a grey or pale iris averts or screens the eyes from the sunlight as much as possible, and in this way escapes the effect of the rays on the face.

(*b*) "Davos Platz, and the Effects of High Altitude on Phthisis." 1881.

(*a*) In a publication on "Davos: its Local, Physical, and Medical Aspects," edited by W. H. Vorman, 1882, the calculation was attempted to be made of the increased weight of fluid exhaled from the lungs in the Alpine climate. 66156·7248 minims were computed to leave the lungs every twenty-four hours. This, although in the right direction, is a most unfortunate and misleading estimation. As the statement has been translated into English, it may not be immaterial to note that such a quantity could not be excreted without an equivalent weight of fluid being taken internally.

Briefly, therefore, a healthy man would in this instance excrete—

From the lungs	137·826 oz.	in 24 hours.
Average evaporation from the skin	24·466	„
Renal excretion (in a cold climate)	60·	„
	222·292 oz.	

He would therefore require to take about 11 pints of fluid during the day and night to meet the loss, and if the skin (which generally excretes 1½ times as much as the lungs) maintained its relative activity a person would have to consume about 20 pints in the 24 hours. Valentine, however, calculates that the fluid exhaled from the lungs ranges from 6 to 27 ounces, the ordinary quantity being 9 or 10 oz.

(*b*) "Danos Platz, and the Effects of High Altitude on Phthisis."

without disgust is eaten promptly. Where improvement begins it is difficult to say; indeed, it is only to a combination of causes that the variety of effects can be attributed. This push to nutrition is a reliable feature in the first evidences of progression, and assures a certain amount of hopefulness in the case.

The exhilarating feeling produced by the *consciousness* of moving about amid snow and ice, without taking cold or feeling pinched, is not to be despised as contributing towards cure. The contrast of this with the life of a consumptive in England during winter, where every change of weather has to be guarded against, is so marked that the hope of recovery presents itself, and despondency is banished.

There is every reason to suppose that under the many favourable circumstances presented by these climates the treatment of suitable cases of consumption and affections of the chest can be undertaken with greater confidence, and those measures which have of late years prolonged many valuable lives in England are certainly most likely to be efficient and successful when supported by the curative effects of mountain air."

(*To be continued.*)

THE FREQUENT REPETITION OF DOSES.

By JOHN W. MARTIN, M.D., M.Ch.,
Sheffield.

The following table of drugs, and their method of exhibition, has been compiled from a recent article in the *New York Medical Journal* by Dr. A. A. Smith, Professor of Materia Medica in Bellevue Hospital Medical College. The subject is one of great interest to practical men. The compiler has frequently found marked benefit to follow a change of dosage, in the direction of smaller amounts and greater frequency of repetition.

Drug.	Dosage.	Disease.
Chlorate of potash.	Gr. j. every half-hour.	Scarlet fever, diphtheria, tonsillitis, &c.
Croton chloral.	Gr. ss. ditto	Neuralgia.
Note.—Solution of a grain to the drachm is almost tasteless.		
Salicylate of sodium	Gr. ij. hourly or half-hourly.	Urticaria (acute).
Note.—Useless in chronic urticaria or that produced by balsam copaiba.		
Fowler's solution.	Gr. ss. half-hourly for 6 or 8 doses.	Vomiting after a debauch. Drunkards' morning vomiting. Vomiting of pregnancy.
Liquor potassii arsenitis.	Ditto.	Ditto.
Jaborandi (fl. ext.), with or without digitalis.	Min. v.—x. hourly or half-hourly.	Produces copious perspiration, without causing any unpleasant heart symptoms.
Sulphate of atropia.	A teaspoonful of a solution of one 1-100th of a grain in a tumbler of water hourly or half-hourly.	Supposed croup, which is usually false croup of a reflex origin.
Note.—If the child's face flushes, and physiological action of drug appears, frequency of dose to be diminished.		
Bromides.	Grs. j.—ij. every 10 or 15 minutes.	Nervous disturbances and transitory disorders of children.
Tr. Chamomille.	Min. j. every 15 or 20 minutes.	Insomnia of nervous, excitable, sensitive children.
Vin. ipecac.	Gtt. j. every 15 or 20 minutes.	Vomiting or diarrhœa.
Calomel.	1-60th of a grain every hour for 10 or 12 hours.	Relieves the headache of syphilis occurring at night.
Note.—It is not to replace the iodides. This is Trousseau's method. The author found it successful by the second or third night.		
Calomel.	Drachm j., every 10 or 15 minutes, of a solution of gr. j. to the pint of water.	Vomiting or regurgitation of food in the case of nursing children.
Hyd. c. cretâ.	Gr. 1-24th every 15 or 20 minutes.	Vomiting and non-inflammatory diarrhœa of children.
Hyd. bichloridi.	Drachm j., every hour, of a solution of gr. j. to the quart of water.	Diarrhœa in children, with mucous passages and inflammatory symptoms.
Tartar emetic.	Drachm j., every half hour, of a solution of gr. j. to the quart of water.	Wheezing and cough of slight bronchitis in children.
Tr. nucis vomicæ.	Gtt. j. every 10 minutes.	Sick headache, not of a neurotic origin.
Note.—To be given immediately or soon after meals.		
Cantharides.	Min. j. every hour.	Vesical catarrh.
Tr. digitalis.	Gtt. j. hourly or half-hourly.	Organic heart disease where digitalis is indicated.
Note.—Gives greater relief without liability to ill effects.		
Castor oil.	Gtt. v. every hour in water, with sugar and gum.	Diarrhœa of children, with straining, slight inflammation and passage of jelly-looking matter, but not true dysentery.
Tr. of pulsatella.	Min. ij. every hour.	Orchitis, epididymitis and dysmenorrhœa, not of a membranous, obstructive, or neurotic character.
Note.—Affords greater relief than any other method of treatment.		
Calabar bean.	Gr. 1-50th every half-hour for 6 or 8 doses. Then stop for 3 hours, and again similarly repeat.	Flatulence, fluttering and palpitation at the menopause.
Ergot (fl. ext.).	Min. j. every half-hour for 5 or 6 hours.	Amenorrhœa, not due to anæmia. To be given the day before and again on the day on which it should occur.
Aconite (tr.).	Min. ⅓ to ½ every 15 minutes.	Febrile disturbance, cold in the head, cardiac hypertrophy with palpitation, severe headache, disturbances of nervous system due to increased force of the heart-beat.
Note.—Effects must be watched. Dose regulated accordingly.		
Hamamelis (tr.).	Min. ij. every half-hour.	Controls hæmorrhages.
Belladonna (tr.).	Min. j. every half-hour for 8 or 10 doses; then cease.	Nasal catarrh and bronchitis with free secretion. Pulmonary œdema, with failure of heart power.
Note.—Retards exudation of serum; overcomes failures of heart power.		
Chloride of ammonium.	Grs. ij., combined with min. x.—xv. of tr. cubebs every half-hour.	Acute pharyngitis, superficial inflammations of the other tissues of the throat.
Note.—If throat inflammations are due to the gouty diathesis, add to mixture min. x. of the ammoniated tincture of guaiac, and give every hour.		
Citrate of caffeine.	Gr. j. every half-hour.	Headache of migraine.
Gelseminum (tr.).	Min. iij. every half-hour.	Neuralgias about the head and face.
Guarana (fl. ext.).	Min. xv. every 15 minutes for 4 doses; then, if no relief, increase to min. xxx.	Headaches, especially those which are periodical and not of malarial origin.

Clinical Records.

ST. VINCENT'S HOSPITAL.

Reduction of Bilateral Luxation of Lower Jaw 9 weeks and 5 days after displacement.

Under the care of Dr. McARDLE.

On the 13th of May, 1883, Mary Donovan, æt. 28, found her lower jaw suddenly fall during the act of yawning, intense pain at the same time shooting across her head and through both ears. On the 17th of July she was admitted into Hospital under the care of Mr. J. S. McArdle, her condition being as follows:—She was weak, emaciated, and very nervous. The dental arches were two fingers breadth apart, every attempt at approximating them ending in failure and producing an aching pain in the temporal and zygomatic regions. Her breath was fœtid, and saliva still trickled from her mouth, the angles of which were in a state of ulceration. She had great difficulty in swallowing, and complained of pain during the almost fruitless attempts she made at speaking. On the 20th July, patient being under the influence of ether, reduction was accomplished and elastic bandages applied to retain jaw in position. Vomiting came on soon after the operation, but did not reproduce the deformity. Six days afterwards the bandages were removed, and now, August 4th, patient can speak distinctly and with comfort. The movements of the jaw are free and painless, and the act of deglutition is performed without inconvenience.

◆

MEDICAL ACT AMENDMENT BILL.

[COMMUNICATED].

In addressing a deputation of medical graduates of the Scotch Universities who appeared before him the other day, in support of university monopoly, Mr. Mundella expressed himself to the following effect:—"It is much to be regretted that in regard to a measure which has for its sole object, after the interest of the public, for that is the first object of legislation, the higher education and status of the profession, the whole battle has reigned around this miserable question of corporation, and that nothing but fees and corporation have been heard in this room *ad nauseam*. It is deplorable that such a noble work and such a glorious profession should come here for no other purpose but to preserve beggarly vested interests, and to see what proportion could be retained of their Parliamentary privileges. I think it is quite unworthy to be considered with the great object we have in view." To this deliverance most people will accord a hearty Amen, and it is stated that the deputation received it with a complacency which put its applicability to themselves quite out of the question. We are pleased to note that Mr. Mundella considers the first object of legislation to be the interests of the people. Now we would ask, how does he propose to serve the best interests of the people "in connection with the question of medical reform?" 1st. He is desirous of strengthening and perpetuating the monopoly in the teaching of science at present possessed by the universities, a monopoly which is incompatible we submit with the "interests of the people," and prejudicial to the science of medicine. 2nd. By giving the Universities of Scotland a large preponderance on the Divisional Board, he aids in preserving "the beggarly vested interests," for which the universities are fighting. The Government monopolists are afraid of fair and honourable competition in the matter of teaching with outside members of the profession, and their "vested interests" must needs be protected by scandalously unfair provisions as to their power in the matter of granting qualifications. In his address to the graduates the other day at the University of Edinburgh, Professor Dickson, one of the lucky Crown monopolists, in denouncing the new Bill, said, with respect to the divisional boards, "there is in the first place the probability, if not certainty, of such friction between the different interests represented on any such board as to make harmonious action impossible, and lead to a state of matters so intolerable *that all concerned would gladly hail a return to the previous conditions*." Precisely so. The "beggarly vested interests" will continue to form a bone of contention between the Universities and Corporations; and rather than that the "beggarly interests" of the Universities should suffer, Professor Dickson would gladly welcome a return to the *status quo ante*. Now what would be the radical and fair remedy for this unseemly wrangling about "beggarly vested interests" between the leaders in science? Why, to take the power of qualifying entirely out of their hands, and let their "interests" depend, as they ought to do, on their ability to maintain them in fair, honourable, and open competition between their peers. In short, the Crown (and no medical reform will be complete which does not proceed on these lines) should institute in behoof of the public, whose interests it professes to serve, a uniform minimum examination qualifying for admission to the register of medical men, *totally independent of the Universities and Corporations as such*. Let the Universities and Corporations still retain the power of conferring "the higher titles" if they will, and show to an intelligent public that they can justify their exalted pretensions apart from "beggarly vested interests." It is a most significant fact that the two leading Scotch newspapers, viz., the *Scotsman* and *Glasgow Herald*, have taken liberal and enlightened views on this matter, at variance with those of Mr. Mundella and his University friends. A Medical Reform Bill the country must have. If passed in its present form the Medical Act Amendment Bill cannot be regarded but as a paltry instalment of a measure too long and unjustly delayed. One of the most depressing features in connection with the whole movement is the anachronism that a Minister of a "Liberal Government" in the nineteenth century makes himself conspicuous as the advocate of a monopoly unjust in its operation, scandalous in its pecuniary selfishness, and indefensible on any grounds of moral or political economy.

◆

British Medical Association.

FIFTY-FIRST ANNUAL MEETING.

In our last we gave a short account of the work done in the Sections up to Section D. We now pass on to

Section E.—Anatomy and Physiology.

The most attractive part of the programme in this Section was undoubtedly the demonstrations of the larynx by Mr. Emil Behnke, who afforded in his own person an admirable view of the vocal apparatus. The oxyhydrogen light illustrations also excited much interest. The papers in this Section were, perhaps on the whole, more interesting to the writers than the listeners. They were valuable, it is true; but the most valuable is not of necessity the most interesting.

Pathology.

In this Section, Dr. Silcock's paper on Some Points connected with the Repair of Fractures, and the discussion introduced by Dr. Shingleton Smith on Cirrhosis of Liver simulating Acute Yellow Atrophy are both worthy of remark; that also introduced by Mr. Paul, on Primary Growths of the Urinary Tract, was of great interest. That, however, introduced by Drs. Mott and Blore, on the

Micro-organisms of Typhus, illustrated as it was by microscopical preparations, not quite so hackneyed as many that are met with on similar occasions, was, to say the least, not behind any of the others, either from the point of view of novelty, or that of completeness in the general "get up" of the subject.

PSYCHOLOGY.

Perhaps in no Section was more important work done than in this. Scarcely in any branch of medicine during late years have more advances been made, particularly in the department of pathology, and as exemplified in the localisation of disease within the brain. The discussion introduced by Dr. Wiglesworth on Bone Degeneration in the Insane was extremely valuable, and also that introduced by Dr. Yellowlees on the Employment of the Insane. Such a discussion as the latter cannot fail, one would think, to be followed by important results. The other subjects treated of were well handled, and the various papers, even to a mind not specially skilled in this department of medicine, seem well worthy of careful study in the quiet of one's own domicile.

OPHTHALMOLOGY.

The most important discussion in this Section was that on the Tests for Colour-sense and for acuteness of vision, with special reference to Schools and Sailors. This discussion was followed by a resolution to the effect—"That in the opinion of the Section it was of international importance that a proper system of testing the sight of seamen be adopted; that there should be an examination by competent persons as to shortness of sight; that the examination by the Board of Trade as to shortness of sight amongst officers and seamen—a subject now entirely neglected—be conducted by competent persons; that the present imperfect examinations as to colour-blindness by the Board of Trade be revised, and also it be extended to able seamen as well as officers; that pilots be submitted to the same test in place of the present varying and unsatisfactory system of examination; and that every person failing to pass such examinations be excluded from the responsibility of the navigation of vessels." This resolution, it was suggested, should be directed to the managers of the School Board schools, who submit pupils to tests; but after some discussion this suggestion was held over. The remainder of the Sectional work was not characterised by anything specially novel or striking.

DISEASES OF CHILDREN.

The discussion opened by Dr. Ballard on the Etiology and Pathology of Summer Diarrhœa may, without imputation on any other, take the first rank in this section. The introducer pointed out how different towns were differently affected, that contrary to the prevalent opinion (which by the bye we consider to be based on incorrect data) summer diarrhœa had no relation to improper food, such as unripe or over ripe fruit, fermented milk, &c., but that it stood in more intimate relationship to temperature. He confessed that much remained to be learned. Next in importance came the discussion on Rheumatism and its Allies in Children. That introduced by Mr. Morrant Baker on Acute Epiphysal Necrosis and its Consequences was important and interesting, and showed the importance of differentiating between this affection and pulpy disease of the same structures. Dr. Gee read an excellent paper on some kinds of Albuminous and Purulent Urine in Children. Dr. Rawdon, the sectional secretary, in his paper on The Operation for Hare Lip, pointed out the importance of early operation, and stated that he had repeatedly operated successfully on the first day of infant life.

OTOLOGY.

In this section the chief interest centred in Inflammation of the Middle Ear, one discussion and no less than three papers bearing directly on the subject; whilst at the same time it formed part of the subject of other papers. The introductory paper by Dr. W. Laidlaw Purves, was acknowledged to be a good one, and covered the ground already gone over recently by Mr. W. B. Dalby.

In the second discussion, that on Varieties of Artificial Tympanic Membrane, the opinion seemed very prevalent, that the most effective and at the same time the simplest form of artificial tympanum was introduced by Yearsley, viz , the cotton pellet.

WEDNESDAY, AUGUST 15, 1883.

SCIENCE AND PSYCHISM.

EARLY in 1882 the Society for Psychical Research was founded, "for the purpose of making an organised and systematic attempt to investigate that large group of debatable phenomena designated by such terms as mesmeric, psychical, and spiritualistic." The constitution of the Society is of a kind to encourage faith in its pretensions, and to justify the belief that a *bonâ fide scientific* endeavour will be made by it to sift the whole mass of statements and experiences which has grown up around the questions that are its peculiar care. It includes a goodly number of eminent and well-known men of reputation in the world of arts, letters, and science, and special committees of its members have for some time been carrying out inquiries in connection with subjects which have elicited considerable discussion both in the press and out of it. Among these "thought reading," or, as it is called in preference, by the Society, "thought transference," has occupied the attention of a committee consisting of Prof. F. W. Barrett and Messrs. E. Gurney, M.A., and F. W. H. Myers, M.A., formerly Fellows of Trinity College, Cambridge. The results at which they have arrived are communicated in two reports printed in the proceedings of the Society, and the second of which contains some details that are intrinsically interesting on account of the assurance they convey of complete absence of intentional deception.

The subjects of the experiments narrated in these reports were, in one case, the daughters of a clergyman, a member of the Society, and in the other two gentlemen who voluntarily offered themselves to the observation of the committee; and it may be once for all accepted that no suspicion of collusion, in the objectionable acceptation of the term, is to be entertained in respect to any of the trials.

The experiments conducted with the children referred to, were mainly based on the power they respectively possessed to divine the thoughts of others who were concentrating their perceptions on a particular object. One set of results with a pack of playing cards is thus given:—"With a full pack of playing cards 248 trials were made with one or more of the committee. Of these 22 were guessed completely right on the first trial, and 18 on the second trial, or a total of 40 quite right out of 248; or one right in not quite 7 experiments." In addition there were 69 cases in which the card was guessed in part correctly. Omitting the second correct guess, these results show one quite right in 11 experiments; if pure guess-work were the explanation there would have been one right in 52 experiments. In the above-mentioned series of trials the sister of the guesser was, as well as the committee, cognisant of the cards selected; but in a second set, during which the committee *alone* knew what had been chosen, 64 trials were made with figures ranging between 10 and 99. The result showed one correct guess out of 13 attempts, whereas pure guess-work simply would give one right in 90 experiments. At a subsequent date, the trials taking place this time in Dublin, Professor Barrett and the subject of the experiment, one of the children, aged 15, were seated alone in a room with their backs to each other: the words "hearts," "clubs," "spades," and "diamonds" were written down by Mr. Barrett, and one of these words mentally selected by him; especial care was taken to prevent any kind of movement which might assist the guesser to divine which of the four terms had been hit upon. Out of 50 trials the worded selected was rightly named 25 times at the first attempt, and a second attempt gave the correct answer in another 10 instances. It is noteworthy too that during the latter half of the time occupied by the experiment the guessing was slower than at first, and less successful, 18 out of 30 first guesses being correct in the former, and but 7 out of 20 in the latter.

In another series of experiments a "young mesmerist" afforded some very remarkable results, which, but for the circumstances under which they were observed, might be received with some degree of incredulity. The transference of *pain* impressions was noticed in the following way:—A sofa cushion was held by one of the committee before the face of S., the "young mesmerist," who was in addition blindfolded, and thus doubly prevented from seeing the person (B.) whose sensations he was to repeat. Another committee-man then pinched or otherwise hurt B., who sat opposite S., holding his out-stretched hand. S. in each case localised the pain in his own person after it had been kept up pretty severely on B. for a time varying from one to two minutes. The results are thus rendered:—

Part of B. made painful:	Answer of S. (by pointing):
Left upper arm.	Left upper arm.
Lobe of right ear.	Lobe of right ear.
Hair on top of head.	Hair on top of head.
Left knee.	Left knee.

The Committee next drew a series of geometrical diagrams, which were then placed in view of B., but in such a way that S. could not possibly perceive them by sight. In each case S. described them correctly, but with the difference that he reversed them in position—*i.e.*, by describing the apex of a triangle, for instance, as below when it was drawn upright, &c. Further, after B. had attentively looked at drawings of the most fanciful description made by the Committee, holding the while S.'s hand (the latter being blindfolded), S. reproduced the drawings in such wise that a close resemblance to the original was apparent, allowing for the blinded condition of his eyes; and in no case was there the smallest possibility that S. could have seen the figure, nor did B. touch S. while the figure was being drawn.

The reality of the phenomena we have been thus particular in describing no longer admits of being doubted; and it is matter for congratulation that their investigation is being undertaken in a sober and practical spirit by those who must be necessarily free from any taint of charlatanism in connection with the researches they devote themselves to. The history of scientific discovery is replete with evidences of the persistent way in which truth is finally evolved out of error, the stages of superstition, credulity, and ignorance being invariably observed in respect to every brilliant demonstration of natural law. It must not be disguised, however, that the time is not yet come when we may hope to see a universally-accepted physical explanation, natural and intelligible, of so-called psychical phenomena. In the very fact of our inability to trace the subtler material changes that herald forth bodily movements and muscular contraction lies the most dangerous factor of our incapacity to elucidate what is mysterious in our less corporeal humanity; and we know only too familiarly how ready an acceptation is given to marvels that do not come immediately within the area of scientific explanation. The Society for Psychical Research is fortunately free from the reproach of arrogance so far: it assumes nothing, but seeks only to understand; and so long as it confines itself to this *rôle* without presuming to erect fanciful theories which cannot have any substantial basis, it will accomplish work of a valuable and abiding character. The tendency of the present day is to import into scientific reasoning that which is absolutely and impossibly unreal. We cannot for a moment sympathise with those who, in the absence of material explanations of "thought transference" phenomena, seek straightway to associate them with a specially invented force called to do duty "for this occasion only." Any encouragement of this propensity of ignorance will be productive of most vicious results; and it is mainly because the Society for Psychical Research steadily sets its face against such spurious science, that it may be expected to do good work. "Thought-reading" is, it is true, but one of the outlets for its energies; but it is a very important one, and has even derived fictitious importance through the association it has with widely-advertised charlatanry. So long as it is permitted to hold the supremacy it now possesses among "the mysteries," it will constantly worry the patience of medical practitioners by swelling the ranks of hysterical and hyperæsthetic malingerers. It consequently deserves their best attention, and they will be helping themselves and the profession by assisting those who are honestly striving to yield a scientific and rational explanation of the phenomena observed.

◆

EXECUTION BY TORTURE.

The scene which was enacted at Durham Gaol on the 6th instant, at the execution of James Burton, can only be described as a disgrace to English civilisation. The process of execution was carried out in the usual way, but after the drop had fallen, a violent oscillation of the rope was noticed. After some futile attempts, the hangman caught the rope, and with the assistance of a warder drew up the wretched man still alive from the pit, upon which it was found that the slack of the rope had caught on the culprit's elbow, and stretching across his face had displaced the white cap. While the rope was being adjusted a second time the culprit was heard to mutter—"Oh! God have mercy on my poor soul;" so that he was not only alive, but conscious and capable of comprehending the horrors of his situation. On the final completion of the toilette of the scaffold he was pushed violently into the pit, and there after a longer or shorter period his sufferings ended. The facts that this miserable and guilty man twice tasted the bitterness of death and underwent physical pain of an excruciating character are not only shocking to all sensitive minds, but are well calculated to neutralise any public benefit that might have been expected to accrue from his punishment, for detestation of the crime for which he suffered is swallowed up in sympathy for the anguish which he endured. He becomes less of a delinquent worthy of condemnation than of an afflicted being deserving of commiseration; and some of the strong reprehension felt towards the manner of his taking off is inevitably reflected on the law which condemned him to death. His sentence was death and not torture, and it was the duty of those charged with his execution to see that it was humanely and expeditiously carried out. The British public does not desire that any unnecessary bodily pangs should be added to the mental anguish of the death penalty, even in the case of the worst and most hardened criminals; and it will certainly not tolerate many repetitions of the hideous scene enacted at Durham.

Our critics of future generations will certainly think it curious that this highly scientific age should have trusted so delicate an operation as the infliction of capital punishment to the bungling of a Lincolnshire cobbler. We have at hand in electricity the means of certain, instantaneous and painless death, and yet we go on using the barbarous apparatus of the rope and drop. So long as we do cling to the ancient institution of hanging we ought at least to see that it is skilfully performed; and in order that we may be assured on that point it is essential that the pit and curtain should be dispensed with, and that an execution should take place in full view of those whose duty it is to witness it. The pit and curtain were steps towards private executions, and were introduced in order to deprive the degraded mobs who used to gather round the gallows of the morbid pleasure of gloating over the death agonies of a fellow creature. But now that executions take place in private there is no longer any excuse for a veiling apparatus. The officials and representatives of the press present should see the whole operation, in order that they may assure the public that it was humanely and properly performed. It should be generally known that the statement now constantly made with reference to executions, that death was instantaneous, is not to be depended on. That is only the hangman's testimony to his own dexterity, and he alone knows what goes on in the pit. When pinioning has been resorted to, death by slow strangulation may take place without any agitation of the rope revealing what is going on below. There are good reasons for believing that even when the long drop is used dislocation of the vertebræ is a comparatively rare occurrence, and that in a large majority of executions death takes place by suffocation. The means resorted to to soothe a gullible public are well illustrated in the case of the convict Burton, whose shockingly mis-managed execution has led to these remarks, and whose countenance is reported to have worn after death "a painless expression." From this it is to be inferred that he suffered little or nothing during his double hanging. But every medical man knows that the expression of the face after death is no criterion of the circumstances under which it took place. Sometimes when death has come suddenly and painlessly or in sleep the features are contorted and suggestive of protracted suffering; and sometimes when it has followed on acute pain or prolonged torment, they are placid or drawn into a smile.

◆

THE MEDICAL OFFICER OF THE OLDCASTLE UNION.

Mr. Healy last week asked the Chief Secretary whether it was the fact that the medical officer of the Oldcastle Union, county Meath, was suspended by a majority of 17 to 6 because of a number of serious charges; whether a sworn inquiry was held, and the doctor admitted on oath the existence of a number of the abuses complained of; whether the Local Government Board notwithstanding removed the suspension, and confirmed the doctor in office; whether the guardians thereupon by a majority of 17 to 6 declared that they had no confidence whatever in the medical officer, and that he should be called upon to resign by the Local Government Board; and whether it was intended to allow this gentleman to retain his post in the face of the protest of the guardians.

The Chief Secretary said the medical officer was suspended on grounds which in the opinion of the Local Government Board did not justify suspension. A sworn inquiry was held into the charges made against him, the first and second of which were very trivial. The third was that he acted disrespectfully to the guardians in employing as an infirmary attendant a woman whom they directed to be placed in the ward for bad characters. It appeared that this woman had been specially trained to attend midwifery cases, and it was this that caused the doctor to employ her. He swore that in doing so he meant no disrespect to the guardians. The Local Government Board considered that in employing this woman he committed an error of judgment, which, however, they considered sufficiently met by an expression of opinion that he had done wrong. They did not think that there were grounds for dismissing him after a period of thirty-three years' service. It was true that since the sworn inquiry the guardians had requested the board to call upon the medical officer to resign, but the board were not prepared to do so in consequence of the facts elicited at the inquiry, although they were willing to give due weight to any charges made.

We have made ourselves fully acquainted with the facts of the case, and are able to say that a more disgraceful attempt by a tyrant majority of politicians and religionists to ruin a deserving and unoffending public officer never came to our knowledge. The truth of the case is that, as soon as this party succeeded in obtaining the upper hand in the board of guardians, its members avowed their intention of weeding out every officer not of their own politics and religion, and they commenced operations with the infirmary attendant, whom they forthwith expelled without asking the medical officer a question on the subject. This woman, being a pauper patient under medical treatment, broke down in health the moment she was removed from the infirmary, and—having gone to a neighbouring medical man—was certified by him as requiring medical care, and was sent back to the house. Thereupon the majority proceeded to get rid of the doctor who had served the union for thirty-three years without a shadow of reproach against his conduct or efficiency, and, to trump up an excuse for dismissal, they went in his absence to the infirmary, broke open his desk, and rummaged his papers—private as well as public. They could, after all, find no cause of complaint, except—*a*. That he had permitted the infirmary nurse to remain in charge—she being the mother of an illegitimate child; *b*. That he had allowed the names of patients in his books to be filled in by other hands than his own. They, however, did not state the fact, and Mr. Healy carefully conceals it in his question, that the illegitimate child was born thirteen years previously, and that during that entire period the woman had borne a good character, and had been permitted to continue in the office by and with the knowledge and concurrence of the board of guardians. If, therefore, there was any fault in retaining the services of the woman, it was the guardians themselves who were to blame.

As to the second charge, everyone knows that it is not unusual for the workhouse medical officers to get part of the clerkship of their books done by deputy, and, in this particular instance, we understand that the medical officer had the formal authority of the Poor-law Commissioners for so doing. No other accusation whatever was brought or could be brought against the medical officer, and yet he was put upon his defence by a resolution of the guardians suspending him and threatening him with dismissal, and was obliged to demand a sworn investigation, out of which he came triumphantly clear.

We presume Mr. Healy goes for the divine right of guardians to crush out an officer with or without cause by the mere force of a majority who do not agree with him in religion and politics, but, thank Heaven! we have not yet come to this condition of affairs.

Until Mr. Healy educates the public up to the creed which he maintains, the "will of the people" as expressed by seventeen political roadside firebrands is not sufficient for the crushing out of a deserving officer who does his duty.

The Irish Local Government Board has acted with propriety in protecting its officer against this persecution, and we trust it will continue to observe the same attitude in similar cases.

◆

Notes on Current Topics.

Telephones for Hospitals.

THE introduction of telephonic communication between the houses of visiting members of hospital staffs and the hospital to which they are attached has, we are informed, been carried out in Glasgow, where the Hospital and Dispensary for Diseases of the Ear is connected by telephone with the aural surgeon's private residence. As this system was adopted in Glasgow, three years ago, it would seem that the departure in the same direction on the part of St. Bartholomew's Hospital authorities is not the first instance of such utilisation of the telephone. It is satisfactory, however, to learn that the plan so recently adopted in London as an aid to hospital work has been found to work well in the great Scotch town; and it may be hoped that an extensive application of this improved mode of communication with the chief medical officers of hospital charities may speedily be witnessed.

More Infectious Disease Legislation.

THE Boston Board of Health has recently issued a regulation that bodies of persons who have died of small-pox, scarlet fever, diphtheria, or typhus fever, must immediately be wrapped in a sheet, saturated with a solution (10 per cent.) of chloride of zinc, and placed in an absolutely tight coffin, which is not to be re-opened. With a similar view, a bill has just been passed by the legislature of Massachusetts, at the request of some railway companies. The bill forbids the transportation through the State of bodies dead of certain contagious disorders, unless they have been so incased and prepared as to preclude all danger of the communication of these diseases through their agency.

Recent Experience in Treating Cholera.

Some interesting notes on an epidemic of cholera which raged at a station in the Madras Presidency from Jan. 11 to March 18 of the present year, are communicated to the *Indian Medical Gazette* by Civil Apothecary F. J. Gonsalvez, who was in medical charge of the station at the time. The writer traces every case which occurred to the same source of infection, viz., drinking water contaminated with the excreta of cholera patients; and he observed that none who obtained their water for drinking purposes from other than a particular stream were affected with the disease. Mr. Gonsalvez appears to have entertained a degree of catholicity in respect to treatment, but at the same time he very freely submits his views to criticism by tabulating the results obtained, whereby the following facts are made clear:—The total number of cases that occurred during the epidemic was 189, of whom 112 died. Of this number 77 were treated by the writer, with 34 deaths; and the remedies employed among them, with the results obtained, are thus given: By sulphurous acid, internally, 16; cured, 9; died, 7. By carbolic acid, administered internally, 20; cured, 12; died, 8. By chlorodyne (store-made), 10; cured, 4; died, 6. By calomel, 15; cured, 9; died, 6; "cholera pills," 8; cured, 5; died, 3. By some other forms of treatment, 8; died, 4; cured, 4. In every one of the cases, however, stimulants were given to the patients, and a free use of sulphur fumigations observed; and Mr. Gonsalvez asserts that in every instance, after the patient had once passed urine, he progressed steadily to recovery. He adds: "I believe astringents are very useful at the very commencement, but when once the true symptoms of cholera have developed, the use of astringents in large doses is very hurtful. In such cases stimulants, warmth, and sulphurous acid or carbolic acid internally, with sulphur fumigation, are the best. Calomel, too, in such cases, is very useful." It is worthy of remark that many persons who drank of the contaminated water stream escaped the infection, and all who were affected ascribed the attack to some other than the true cause; wherefore Mr. Gonsalvez very tritely assumes that cholera poison does not attack a person so readily unless he is suffering at the same time from diarrhœa, dysentery, or some other bowel complaint. More definite observations in respect to this are surely desirable.

The Registrar-General's Quarterly Return.

The return of births and deaths occurring during the quarter ending June 30th last, and which is issued under the direction of the Registrar-General, shows the number of deaths in the United Kingdom to have reached 181,453, while 293,074 children were born. In England alone 228,703 births were registered, this giving an increase of 1,274 over the corresponding period of 1882, and equal to a rate of 34·3 per 1,000 of estimated population. During the quarter England contributed a total of 133,783 deaths to the register, being equal to a rate of 20·1 for the whole country. Though exceeding the exceptionally low rate of the two preceding years by 1·5 and 1·1 respectively, the figure is still 0·3 under the average for ten previous corresponding quarters, and its increase over that of 1881 and 1882 is ascribed to the unseasonably low temperature that prevailed in March last. Of the causes of death, zymotics have to answer for 12,632, or equal to an annual rate of 1·89 per 1,000, a considerable reduction on the average, and a lower figure than any since 1870, except that—1·87—of 1881. The diseases contributing to this group of deaths, and the numbers carried off by them, are—whooping cough, 2,815; measles, 2,582; scarlet fever, 2,452; diarrhœa, 1,905; "fever," 1,793; diphtheria, 861; small-pox, 224. This last named, small-pox, is chargeable with a declining number of deaths as compared with the first quarter of the year, and the principal areas of the activity shown by it were London, Newcastle-on-Tyne, and Staffordshire. The death-rate of watering-places is shown to contrast very favourably with that of other towns in England; it reached 17·9 in the aggregate of forty-six such health resorts mentioned in the returns.

The Destruction and Utilisation of the Bodies of Animals Dead of Charbon and other Infectious Diseases.

For the last few years it has been customary to bury the bodies of animals dead of infectious diseases, but since M. Pasteur has written his work on the vitality of the *charbon* spores, and their transmission to the surface of the soil by means of worms, the question has arisen: "What is the best way to destroy the life in these germs of disease?" Two ways have been suggested—first, that of burning the body entirely; and second, that of cutting it in pieces, cooking it at a temperature of 100 degs., and using it then for pigs' food. But these proceedings are liable to be imperfectly carried out, and in either cases if the heat is hot sufficiently great the danger of infection remains unaltered. M. Aimè Girard brings before us a plan for dissolving the body of the animal in cold concentrated sulphuric acid, and using the liquid thus obtained for the production of a nitrated superphosphate of lime. He says that 48 hours after the body of an animal has been placed in a bath of the acid, it has entirely disappeared—bones, flesh, muscle and skin, or wool, are quite gone, and in their place is only left a coloured fluid floating on the surface of the fat which has been liquified by the heat of the reaction. M. Roux inoculated some animals with this fluid, but found it produced not the slightest ill result. The azotised sulphuric acid still retains its power of fertilisation after the bodies have been dissolved, and therefore can be sold to the farmers at a good price. This has been proved by M. Aimé Girard, who, after the price of the chemicals had been deducted, made a profit of about 37 francs on the sulphuric acid in which the bodies of 9 sheep had been dissolved, viz., an average of 4 francs for each animal.

In an autopsy on a patient dying in one of the Vienna hospitals, there was found in his brain an iron nail covered with rust, which to all appearances must have been there since early childhood. The man was about forty-five years of age, a bookbinder, and always passed for intelligent. Negative popular evidence is of but little value. The man, at regular intervals, had epileptic attacks, and post-epileptic mental phenomena, while in the hospital.

Cremation as a Prophylactic.

Dr. Domingos Freire of Rio de Janeiro has recently reported experiments in which he has communicated yellow fever to fowls and guinea-pigs primarily by injection of blood from the heart of a deceased patient, afterwards by transmission from one animal to another, and also by confinement of a guinea-pig for five days over earth from the grave of a yellow-fever patient buried a year before. In consequence of his representations of the great peril created to public health by the inhumation of persons dead of yellow fever, the Minister of the Empire has, according to the *Anglo-Brazilian Times*, ordered the Director of Public Works to proceed to the erection of a furnace at Jurujuba, for the purpose of cremating the bodies of those who die there of yellow fever in the hospital, in whose neighbourhood, in fact, yellow fever has now appeared among the local population.

Sand and Deafness.

Obstinate deafness is frequently created by the influence exerted over the ears of persons catarrhally inclined who resort to sea-bathing along the shallow sandy shores that are the ideals of those who delight in the delicate titillation of their bodies by the accumulated rubbish suspended in the water in such situations. This point is especially commented on by Dr. Edward Woakes in a brief manual on "The Hygienic Management of the Catarrhally Predisposed," which he has just published through Mr. H. K. Lewis. The whole subject of the warning contained in the *brochure* is one well worthy of very extended consideration; and it is hardly possible to disguise the fact that it rarely receives its due importance at the hands of the general practitioner. In this matter of injury done to the ears by bathing and diving, it may safely be assumed that many cases of mysterious aural mischief might be satisfactorily cleared up by an appeal to the patient's history in connection with holiday exercises.

Fatal Accident to Dr. Langdon Down's Son.

A general feeling of sympathy has been excited with Dr. Langdon Down and his family in the dreadful affliction under which they are suffering from the death of Dr. Down's eldest son. The unfortunate young gentleman, who was just twenty-two years old, and held a lieutenant's commission, was with a younger brother engaged in amateur carpentering in the establishment at Normansfield with which Dr. Down's name is inseparably associated; and by some mischance a chisel that he was using slipped and pierced his femoral artery, hæmorrhage from which was the cause of death. The universal esteem felt towards Dr. Down personally will intensify the regret awakened by this domestic calamity; and while nothing can lessen the terrible nature of the blow, the outburst of spontaneous sympathy given to him may at least somewhat soften its effect.

An anonymous benefactor has written to the authorities of the Wigan Infirmary, offering to erect and furnish, at a cost of £3,000, a wing to the present buildings, with the special object of providing separate wards for severe cases and such as require isolation.

Cotoin for Cholera.

In view of the great anxiety which has been excited by the outbreak of cholera in Egypt, a circular has been issued calling attention to the specific action of cotoin upon the bowels. For internal administration the use of an emulsion containing 1 gram of cotoin in 120 is recommended, a tablespoonful to be taken every quarter or half an hour; or cotoin may be given as a powder in doses of 0·2 gram every half hour or hour.

Another Nursing Trouble.

For some time past it has been evident to those acquainted with the working of King's College Hospital that a nursing trouble in that institution could be only a question of time. For years we have been accustomed to hear smothered complaints of the autocratic government insisted on by the matron; and it is notorious that her aggressive attitude has caused much justifiable discontent among students and staff. At length, however, the acme of toleration has been reached, the resignation of the matron insisted on, and, after prolonged refusal, received. That the lady would cling to her position as long as possible is to be expected; but what is really incomprehensible is that her subordinates, the sisters, all educated women, should so far forget the traditions of charity and duty as to make the forced resignation of their principal an excuse for their own withdrawal from the wards without previously giving notice of the intention. All honour, be it added, to the nurses who, notwithstanding the absence of pretensions claimed by "lady" nurses, remained with true womanly pity at their posts beside the beds of suffering patients, the while their cultivated "superiors" followed in the wake of the indignant matron. Spite of the temporary inconvenience, the authorities of King's may congratulate themselves on a good riddance of women who could be guilty of so grave a dereliction of duty; and we trust the incident may serve as a final warning to hospital authorities to insist, once for all, on nurses doing nurses' work, and accepting the only position in which they can be serviceable, that, namely, of subordination to the medical staff.

The Treatment of Epilepsy.

In the course of an interesting lecture on epilepsy, translated from the French of Prof. B. Ball, by Dr. E. P. Hurd, and published in the *North Carolina Medical Journal*, May, 1883, the author deprecates the prolonged use of the bromides, which, while giving excellent results from the point of view of the convulsive attacks, may, in the long run, bring about a sensible impairment of the mental faculties. He prefers the mixed treatment, associating oxide of zinc and belladonna with the alkaline bromides.

At an ordinary meeting of the Council of the Royal College of Surgeons of England, held on Thursday last, the Honorary Gold Medal of the College was unanimously awarded to Mr. Richard Owen, C.B., F.R.C.S., F.R.S., in recognition of his very numerous and important contributions to biological science, and of the valuable services which he rendered to the College while he was Conservator of the Museum and Professor of Anatomy.

Sanitation in Dublin.

A few years ago the columns of our journal were largely occupied by adverse criticisms upon the sanitary administration of Dublin by the Public Health Committee of the Corporation. At that time, in truth, nothing could be worse than the condition of things brought about by the inaction of the Committee and its officers—the mortality of the city was horrible to record, and the state of the tenement houses digusting and abominable, and no serious attempt was made to improve the condition of affairs. The Dublin Sanitary Association had almost exhausted itself in remonstrances, suggestions, and efforts to galvanise the Committee into action, and it was not until the Royal Commission of Inquiry, which had been resisted and impeded in every way by the Corporation and the Irish Local Government Board, had made its report that the civic authorities were stirred to an appreciation of the enormities of Dublin insanitation. The Public Health Committee was, in fact, at that time paralysed by the worthlessness of some of its officers, and by the presence therein of a majority of members who had inherited a policy of lethargy from past years of inaction, and who outvoted a few earnest men such as Mr. Gray and Mr. Dawson, in the effort to amend matters.

We should not be doing justice if we did not now give spontaneously to the Committee and its chief officer, Dr. Cameron, as large a measure of praise as we did then of blame. We are truly glad to say that since Dr. Cameron's accession to office, and since the Committee has been weeded of obstructives, an immense improvement has taken place, not only in the sanitary administration of the city, but in the health of its population resulting therefrom. The Committee seems to us to be really doing its best with the materials at its command, and an immense deal has been achieved which has borne fruit in the materially improved health of the citizens. The money at the disposal of the Committee has been, as far as we can see, expended judiciously, and, speaking generally, a vitality is apparent in the sanitary administration of the city which was lamentably absent in times past. We say this not only in fairness to the Committee and its officers, but as a stimulus to them to persevere. As yet but little of the insalubrity of the city has been amended, and progress must necessarily be slow. There are years of steady work before the Committee and Dr. Cameron before Dublin can take its place as a fairly healthy, well-kept city, and we earnestly trust that there will be no want of perseverance and energy on their part. We are glad to recognise in the Committee a determination not to flinch before the opposition of slaughter-house and dairy-yard proprietors and other owners of vested nuisances, and we hope that firmness of purpose will be maintained.

With a view of securing better collections for the Hospital Saturday Fund, we understand that the Council have issued 30,000 collecting sheets to the various workshops of the metropolis, and to police, postal, railway, and other officials. Boxes will be placed on board all the Thames ferry-boats. 300,000 illustrated handbills are being printed for circulation, and the occasion will further be made known by advertisements upon omnibuses and tramways.

Immunities from Cholera.

According to some writers, persons employed in certain occupations enjoy a greater or less immunity from cholera. At Bellary, in 1859, the coolies employed in connection with lime kilns were said to be exempt from the disease. There exists a belief in India that this class of labourers generally enjoy such exemption. During the epidemic in France in 1865 persons exposed to the inhalation of gas from oil were said to have escaped; no such exemption, however, was enjoyed by persons employed in the manufacture of ordinary coal gas. In 1720 the tanners at Marseilles are said to have enjoyed exemption from plague. In 1865 they enjoyed a similar exemption from the epidemic of cholera then raging. In the latter year workers in the copper mines between Toulon and Marseilles were exempt from the disease, their immunity being by some writers assigned to the fact that they thus inhaled a certain quantity of copper dust. Surgeon-General Gordon, in his "Hygiene of Cholera," mentions that in India persons employed in the manufacture of gunpowder are considered to have a similar freedom from cholera. In the epidemic of cholera at Lauffen in 1865, of the inmates of the prison at that place joiners suffered most, agricultural labourers fared best; between those extremes came ropemakers and tailors. Certain writers, bearing in mind that workers in copper appear so far to be as a class exempt from attacks of cholera during epidemics of cholera, have recommended the wearing of plates of that metal in the manner of talismans or charms against that disease. According to the principle thus adduced, a piece of quicklime, a little gunpowder, or perhaps better still, a strip of half-tanned hide would be equally effectual. Perhaps, and much more probably, they would be equally ineffectual.

In the Report by the Commission on the epidemic of cholera in France in 1832—1865, it is stated in regard to various methods of treatment reported on, that "sulphate of copper, reported on favourably in one place, was condemned in others." Homœopathy was employed in many places. "At Dieuville, of 16 cases thus treated, 14 died; at Marseilles, in 1854, out of 26 similarly treated, 21 died."

Lawyers' Unqualified Assistants.

The Dublin papers have recently contained the records of several applications made to the Judges to admit solicitors' apprentices to practise, notwithstanding their being deficient of a part of their apprenticeship. These appeals have been all made under specially moving circumstances, but nevertheless have been, one and all, resisted by the Law Society and refused by the Judges, who declared that it would be monstrous to permit an apprentice to act for a client even in the pettiest capacity until he had put in his full term of service.

It would seem, therefore, that sham certificates and short education, which are the currency of our profession in some educational centres, are not tolerated by the lawyers, and that an educational incompetency which is quite good enough when life and health are in the scale, is not allowed when property is the consideration at issue.

This has been specially illustrated by a decision given in London last week in a case in which a solicitor employed two unqualified assistants. Mr. Justice Field and Mr. Justice Watkin Williams had before them the matter of one Whitmarsh, a solicitor, and others, in which the Law Society called upon Mr. Whitmarsh to show cause why he should "not be struck off the rolls," and upon two other persons, to show cause why they should not be punished, the former for having allowed the others to practise in his name, and the latter for having so acted as solicitors, one being a clerk in a solicitor's office and the other an ironmonger. Whitmarsh was struck off the rolls and his assistants each imprisoned for three months.

The blood-curdling atrocity of which these "unqualified assistants" had been guilty was that they filled up some writs, a crime too horrible for palliation. If Whitmarsh had been a general medical practitioner, had kept half-a-dozen district "surgeries," had allowed the unqualified to treat, physic, and kill or cure an unlimited number of patients, and had filled up any number of false death-certificates, he might, according to the public view, be very reasonably allowed to pursue these practices *ad infinitum*, and his unqualified assistants would have been welcomed to the profession whenever they pleased to enter it. But it was simply too horrible to think of any man filling up a writ (or taking a fee) until he had duly served out his indentures. Truly, "one man may steal a horse while another may not look over the hedge."

Awards from the Hospital Sunday Fund.

We referred in our last to the meeting of the Distribution Committee of the London Hospital Sunday Fund for the purpose of deciding upon the awards for the present year. Unfortunately the early promises on Hospital Sunday of a larger collection were not realised, the amount ultimately falling short of last year by about £4,000; consequently the institutions concerned are short of that sum, and there are three more to participate. The following is the official list of awards:—General hospitals: Charing Cross, £731 5s.; French, £230 12s. 6d.; German, £731 5s.; Great Northern, £225; King's College, £1,462 10s.; London, £3,011 15s.; Metropolitan Free, £231 5s.; Poplar, £315; Royal Free, £450; St. George's, £1,677; St. John and Elizabeth, £123 15s.; St. Mary's, £1,065 3s.; Seamen's, £787 10s.; the Middlesex, £1,518 15s.; Tottenham Training Hospital, £223 15s. 11d.; University College, £1,004 4s.; West London, £309 7s. 6d.; Westminster, £900. Special hospitals: City of London Hospital for Diseases of the Chest, £731 5s.; Hospital for Consumption, Brompton, £1,250; North London Consumption Hospital, £257 17s.; Royal Hospital for Diseases of the Chest, City Road, £225; and Royal National Hospital for Consumption, £337 10s.

Mr. Anderson, Surgeon to H.M.S. *Stork*, has met with a fatal accident. During a trip up the Mayumba river a hippopotamus was wounded, and charged the boat, which was capsized, and three out of its four occupants, including the surgeon, were drowned. Mr. Anderson was making his first voyage as a naval surgeon.

Telephones for Dublin Hospitals.

The Meath Hospital has been connected by telephone with some members of its surgical staff. It is the sixth hospital in Dublin which has thus been brought into direct communication with its responsible officers—the others being the Richmond, Jervis Street, Mater Misericordiæ, Cork Street Fever Hospital, and the Dublin Orthopædic. Stevens's Hospital and the Coombe Lying-in Hospital—each of which are nearly two miles distant from the residences of their responsible surgical officers—are not yet "joined up," and are consequently dependent for emergencies upon their resident officers. Other hospitals, such as Sir Patrick Dun's, the Adelaide, Mercer's, and the City of Dublin Hospital, are within easier reach of their surgeons, but are, nevertheless, not—as they ought to be—within call of their staff. The inconvenience and injury to the patient by delay in sending off messengers to look for the surgeon whenever an accident occurs is less in their case, but is, after all, only a matter of degree. We do not see why the sick or injured should have to wait an avoidable moment for surgical help, and we, therefore, hope soon to see every hospital surgeon in Dublin in direct communication with his hospital.

A Cholera Bulletin.

It always affords some degree of interest, if not always of pleasure, to learn the opinions of our neighbours regarding us and our doings. For this reason we devote a few minutes to the consideration of a curious article that appeared under the above heading in our contemporary the *Wien. Med. Zeitung*, under date of July 31st. One thing we may premise—whatever may be thought of the substance of the communication, the style will assuredly not fail to commend itself to all who are of opinion that "tall" writing and "effect" are the first *desiderata* of composition:—

"Europe looks anxiously to the land of the Pharaohs, and listens eagerly to the Job's posts that daily arrive from the Nile Deltas. The dark stranger which English ships have carried from India to Egypt gains more and more in power, the number of victims already amounts to myriads, and the destroying angel forces its way farther and farther into the country. The Khedive descends from his throne, visits the head-quarters of the pestilence, Cairo, inspects the hospitals, comforts the inhabitants almost at death's door, and personally takes the necessary measures. Oriental fatalism flees not from the dark-visaged stranger, but looks him calmly in the face, for Allah has sent him; the apathetic Fellah, brought up in noisome filth and the most extreme want, neither seeks nor expects aid, especially from his deadly enemy, the Englishman. With brutal indifference, the English for five weeks permitted the cholera to become rampant over a greater and greater extent of territory; and whilst they knew how to scrutinise sharply the taxes of the country, its in and outgoings in raw and manufactured products, they did not trouble themselves in the least about the guest from the Ganges and the Bramaputra, who with his poisoned arrows was murderously stalking through the land. At first Old England laughed at terrified Europe, but afterwards apparently collected herself and—sent physicians to Egypt to *study* the cholera and its progress on the spot."

The article contains more, much more, of this hysterical nonsense. The writer, if he ever had any wits, has plainly been *erschreckt* out of them by the *schwarzem Gast vom Ganges und Bramaputra*. It is not necessary to make further comments on such a ridiculous production, in which imagination and spleen have performed the duties that ought to have devolved upon reason, and which would have been unworthy of notice on our part had it not received an official stamp as an editorial.

Irish Sanitary Authorities.

In answer to Mr. Gray, the Chief Secretary stated last week that the number of sanitary authorities in Ireland was 223, of whom thirty-three had adopted bye-laws under the Public Health Act. Boards of Guardians were at present entrusted with the duty of making provision for special hospital accommodation, but it would be better and more convenient in some of the large towns if the same powers were given to the urban sanitary authorities —viz., the corporations and town commissioners.

The epidemic of diarrhœal diseases continues in Berlin with alarming severity. Last week there were 679 fatal cases. In New York there were 180 fatal cases; London, 168; Philadelphia, 142; Paris, 131; and St. Petersburgh, 130.

Dr. Robert Moffat, the celebrated African traveller and missionary, died last week at Brighton, at the age of 88. Dr. Moffat's daughter was the wife of the late Dr. Livingstone, and was almost as well known for her devotion to African work as her father and husband.

A new ambulance steamer, built for the Metropolitan Asylums Board for the conveyance of small-pox patients down the river Thames to the small-pox ships lying off Purfleet, and also to the new convalescent hospital about to be erected at Darenth, was launched last week from the Milwall Dock. The steamer has been specially constructed for the purpose, at a cost of £4,500, and was christened the *Red Cross*.

Professor Hoffman, the eminent chemist of the Berlin University, unveiled a colossal monument at Munich last week to the memory of Liebig, Helmholtz, and Lepsius. A sum of more than 150,000 marks was collected, and this amount was large enough to enable the promoters not only to erect the monument at Munich, but to order a copy of it to be set up in front of the University of Giessen, where Baron von Liebig first attained eminence as a chemist.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Plymouth 9; Cardiff, Derby, Birkenhead, 11; Brighton 13; Bristol, Halifax, Hull 15; Wolverhampton 16; Dublin, Norwich 17; Leicester, Portsmouth, Bolton 18; London, Bradford, Nottingham, Salford, Blackburn 19; Edinburgh, Birmingham, Sheffield 20; Oldham, Sunderland 21; Leeds, Huddersfield 22; Manchester 23; Glasgow 24; Preston 27; Liverpool 28; Newcastle-on-Tyne 33.

A scientific expedition has been despatched from Berlin to Egypt to examine into the origin, nature, and course of the cholera epidemic, and to ascertain what are the best measures of precaution against the disease. The expedition will be under the control of Privy Councillor Koch, a member of the Imperial Board of Health, and will leave next week for Alexandria.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 23, Bombay 26, Madras 31, Paris 23, Geneva 15, Brussels 28, Amsterdam 26, Rotterdam 18, The Hague 25, Copenhagen 23, Stockholm 21, Christiania 11, St. Petersburg 29, Berlin 63, Hamburg (State) 30, Dresden 31, Breslau 33, Munich 36, Vienna 23, Prague 37, Buda-Pesth 36, Trieste 26, Rome 24, Turin 29, Venice 27, Lisbon 28, New York 29, Brooklyn 27, Philadelphia 32, Baltimore 29.

The use of medicated gelatine as an application in skin diseases has been reported on very favourably by Messrs. Unna and Bieirsdorff. Various medicines are used, of which the preparation of chrysarobin may be taken as a type. It is made by dissolving 50 parts of dry white gelatine in 100 parts of water in a water-bath, then mixing with diligent stirring 10 parts of chrysarobin. When required for use a small quantity is melted and spread upon the skin with a camel hair pencil; the gelatine soon hardens, and to prevent it from cracking should be painted with a little glycerine. Applied in this way, after a warm bath, the chrysarobin gelatine dressing requires renewal only two or three times a week, even in serious cases of psoriasis.

In the large towns last week the death-rates from the principal zymotic diseases were highest in Sheffield, Preston, Liverpool, and Newcastle-upon-Tyne. The death-rates from measles were 2·9 in Liverpool and 5·9 in Newcastle-upon-Tyne; from scarlet fever, 1·2 in Sheffield, 1·8 in Birmingham, and 2·4 in Leeds; from "fever," 1·4 in Halifax, and 1·8 in Liverpool; and from diarrhœa, 2·6 in Sheffield, 4·0 in Leicester, and 4·8 in Preston. The death-rate from diarrhœa was equal to 2·2 in London, and averaged 1·5 in the provincial towns. The 26 deaths from diphtheria included 16 in London, and 2 in Edinburgh, Glasgow and Leeds. Small-pox caused one death in London, one in Birmingham, one in Sunderland, and one in Newcastle-upon-Tyne. The entire mortality is much below the average.

◆

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

Outbreak of Fever in Skye.—An outbreak of fever, apparently of a somewhat serious character, has occurred at the township of Elgol, on the estate of Strathaird, Skye. The fever is said to be typhus. There are about 40 houses in the village, and in a number of these cases of fever are reported. Some of the details are said to be very distressing. In a cottage of one room, it is stated that a widow and six children are all lying ill together. The medical officer who attended the people affected by the epidemic has himself caught the contagion, and is lying ill at Broadford, where it is rumoured other cases have occurred. The outbreak of this malignant fever is one which apparently calls for prompt measures on the part of sanitary authorities. The township of Elgol is situated in the parish of Strath, opposite the Island of Soay, and quite close to the famous Spar Cave.

Artistic Fair at Dunoon.—On the 9th inst. a grand artistic fair was opened at Dunoon by the right hon. the Earl of Glasgow. The object of the bazaar is to purchase a small cottage of four or six beds in which poor people requiring hospital treatment, belonging to the district, could be better treated than in their own homes. His Lordship said he regretted that the Duke of Argyll had not been able to open the bazaar, but he had very much pleasure in doing so in his absence. This was not the first time that he had visited Dunoon in connection with a work of charity, because Dunoon was well known over the West of Scotland for the Convalescent Homes founded by Miss Clugston. This was not a competitive institution. It was rather a parallel one. The institution covered one class of cases, the Cottage Hospital covered another. He was well aware that some persons had questioned the utility of bazaars, but they must be judged by their results, and it must be remembered that there were many who could give their time and skill to the relief of suffering who could not give money. Having referred to the special objects of this bazaar, his Lordship said they required a sum of at least £1,000, and he was glad to hear that already many had guaranteed a bed for the next five years.

Health of Edinburgh.—For the week ending with Saturday, the 4th inst., the mortality in Edinburgh was 87, and the death-rate 19 per 1,000. Diseases of the chest accounted for 40 deaths, and zymotic causes for 10, of which 2 were due to diphtheria, 3 to scarlatina, and 4 to measles, the intimations of these diseases for the week being 6, 37, and 62 respectively.

Action against a Druggist.—In the Aberdeen Sheriff Court, on Saturday, the 4th inst., a compromise was effected in the action at the instance of Mrs. Joanna Campbell or Williamson against John Sangster, druggist in Aberdeen, in which £750 was asked for as damages for the loss of the pursuer's husband. The circumstances of the cases were peculiar. The pursuer purchased from the defender's shop a quantity of salicylate of soda, which she ascertained after reading in the variety column of a weekly periodical was a specific for the ailment from which her husband was suffering. She administered a dose of the drug to the patient, who soon after died. The pursuer's averment on which the action was founded was that the drug purchased from the defender was not of the nature of salicylate of soda, but was an injurious article, and had caused her husband's death. The defender denied this averment, pleaded that the same drug had been sold to other customers without producing any pernicious effect, and that the death of the pursuer's husband was due to other causes. The defender has, however, now agreed to pay £400 to the pursuer in full of all damages sued for, and expenses.

Glasgow.—City Death-rate.—The deaths in Glasgow or the week ending with Saturday, the 4th inst., were at the rate of 25 per 1,000, as compared with 22 in the preceding week, and 24, 24, and 25 in the corresponding periods of 1882, 1881, and 1880.

Executions.—A short time ago, in connection with a horrible double execution in Glasgow, we felt compelled to advert to the inhumanity of the procedure, and the degrading effects necessarily produced thereby in the public mind. Durham has, the other day, been the scene of an act which is an outrage to humanity, and once more compels us to ask how long this sort of thing is to continue in a country professing Christian principles? Thackeray, in describing a public execution, remarks: "I fully confess that I came away down Snow Hill that morning with a disgust for murder, *but it was for the murder I saw done*. . . . . I felt myself ashamed and degraded at the brutal curiosity which took me to that brutal sight. I pray to Almighty God to cause this disgraceful sin to pass from among us, and to cleanse our land of blood." We fervently do likewise.

A New Medical Test for Rape.—At a recent trial for rape before the High Court of Justiciary, the medical man who examined both the plaintiff and the accused stated in his written report that: "On pushing back the foreskin of the penis of the accused there was an odour perceptible peculiar to woman."

Glasgow Royal Infirmary Appointments. — At a meeting of the directors of the Glasgow Royal Infirmary, held on the 8th inst., Dr. Angus McPhee was appointed an Extra-Dispensary Physician; Dr. John Barlow, Lecturer on Physiology; and Dr. James Provan, Physician to the newly-formed Department for Skin Diseases. These appointments have given great satisfaction in the profession.

Edinburgh University Prizes and Scholarships.—The following is a complete list of the prize-takers, the awards being made at the capping ceremonial on August 1st:—The Ettles Scholarship for 1883 has been awarded to William Hunter, M.B., C.M. The Beaney Prize has been awarded to William Hunter, M.B., C.M. The Buchanan Scholarship has been awarded to John William Ballantyne, M.B., C.M. The James Scott Scholarship has been awarded to George Forbes Alexander, M.B., C.M. The Dobbie-Smith Gold Medal has been awarded to John R. Henderson, Student of Medicine.

University of Aberdeen.—Medical Graduation.—The ceremony of capping the medical students at Aberdeen University who have passed their professional examinations during the past six months took place in the Public School, Marischal College, on Friday last. The hall was crowded with an assemblage of ladies and gentlemen. Principal Pirie presided, and there was a large attendance of the University professors. In the course of the proceedings the students indulged in outbursts of hilarious academic fun, but on the whole the ceremony was unmarred by the disorderly exhibitions that were wont in recent years to characterise it.

Scottish Universities, Salaries and Pensions.—The subjoined return moved for by Mr. Dalrymple, has just been published. It shows what a valuable position that of a Scotch Professor is, and gives a very tangible explanation of the tenacity with which the Professors cling to a wicked monopoly, in which, strange to say, they are encouraged by a "liberal government:"—Edinburgh—George James Allman, Professor of Natural History and keeper of Museum, amount of pension £385 0s. 6d., age when granted 58, date 25th October, 1870; John Hutton Balfour, Professor of Botany and keeper of Botanical Gardens, £1,144 2s. 5d., age when granted 71, date 19th August, 1879; John Stuart Blackie, Professor of Greek, £868 8s. 10d., age when granted 73, date 19th August, 1882. Glasgow—Edmund Law Lushington, Professor of Greek, £862 13s. 1d., age when granted

64, date 14th May, 1875; Allen Thomson, Professor of Anatomy and Botany, £842 14s. 4d., age when granted 68, date 12th July, 1877; Hugh Blackburn, Professor of Mathematics, £1,073, age when granted 56, date 15th August, 1879; John B. Cowan, Professor of Materia Medica, £153 9s. 4d., age when granted 51, date 27th February, 1880. University of Aberdeen—William Martin, Professor of Moral Philosophy, £366 17s. 6d., age when granted 60, date 28th June, 1876; George Ogilvie Forbes, Professor of Institutes of Medicine, £151 12s. 3d., age when granted 56, date 14th August, 1877; Alexander Harvey, Professor of Materia Medica, £219 9s., age when granted 67, date 28th October, 1878; Alexander Bain, Professor of Logic, £344 13s. 7d., age when granted 61, date 20th May, 1880. University of St. Andrews—W. L. F. Fischer, £322 7s. 4d., age when granted 64, date 1st October, 1877; William Swan, Professor of Natural Philosophy, £211 4s. 8d., age when granted 61, date 10th January, 1880.

BEQUESTS TO THE DICK VETERINARY COLLEGE AND THE UNIVERSITY OF EDINBURGH.—Under the will of Miss Mary Dick, it is provided that, after the payment of certain legacies, the residue of her estate, with the accumulations of the free income to be derived from the same, shall be held by the trustees of the testatrix until it amounts to £20,000, when it shall be divided into two equal portions, £10,000 being applied in the furtherance of veterinary science in connection with the Veterinary College, and the other £10,000 in the founding of a Professorship, either of comparative anatomy or of surgical anatomy, whichever of these Chairs her trustees shall consider to be most required in the interests of medical science, in the University of Edinburgh, "in memory of the late Dr. John Barclay and the late Professor John Goodsir." Of the trustees under the will, Professor Turner, Professor Chiene, and Professor M'Kendrick (Glasgow) are declared by the testatrix to have been appointed "in consequence of their special qualifications to carry out" her wishes "in regard to the disposal of the residue" of her estate.

GLASGOW.—HOSPITAL ACCOMMODATION FOR INFECTIOUS DISEASES.—Dr. James B. Russell, the Medical Officer of Health for Glasgow, has just issued an important memorandum on the hospital accommodation for infectious diseases in the city. Discussing the question of what ought to be the extent of the accommodation, he expresses the opinion that the minimum requirements cannot be estimated at less than from 550 to 600 beds for fever, and 150 for small-pox. The accommodation at present consists of 340 for fever, being 220 at Belvidere and 120 at Parliamentary Road, and 150 for small-pox—all at the former hospital. It has been determined to erect seven new pavilions at Belvidere, which will bring up the fever accommodation there to 330 beds, and it has been suggested that other three should be put up in order to make 400. On the whole, he thinks the management of such an hospital as this must be regarded as a somewhat doubtful experiment, as there is at present no infectious hospitals with so many permanent beds in the kingdom. The memorandum concludes with suggestions as to the structure and administration of Belvidere hospital, and observations on the clinical study and scientific investigation of infectious diseases.

THE REGISTRAR GENERAL'S RETURN.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, August 4th, states that the death-rate was 21·6 per 1,000 of estimated population. This rate is 0·3 above that for the corresponding week of last year, and 3·1 above that for the previous week of the present year.

Medico-Parliamentary.

HOUSE OF COMMONS.—THURSDAY, AUGUST 9TH.

PAUPER LUNATIC CHILDREN.

IN reply to Mr. S. Leighton, Mr. MUNDELLA said from 1871 to 1882 the increase of 369 pauper lunatic children was due to the increased population, to the advantages of the better treatment of idiots in licensed houses, and to the fact that a Government grant was given in 1875 for the maintenance of this class of children in asylums. The Chairman of the Lunacy Commission (the Earl of Shaftesbury) informed him that an insane child was rarely met with, and that lunatic children did not suffer from monomania or dementia, but that they were generally idiots and imbeciles from their birth, and required special care and treatment. The noble earl also informed him that in his opinion seven-tenths of the lunacy in the country was due solely to intemperance.

THE CONTAGIOUS DISEASES ACT.

Lord E. CECIL asked the First Lord of the Treasury whether, in view of the enforcement of the provisions of the Contagious Diseases Act, and of the great increase of disease that had taken place in our seaport towns, as well as the abandonment by the Government of all legislation upon the subject this year, he could assure the House that, as far as lay in the power of the Government, police assistance should be given as heretofore to enforce the law; and that, pending future legislation, the health and efficiency of our Army and Navy should not suffer by the departmental negligence of the Executive during the recess.

Captain PRICE asked the Prime Minister whether he was not aware that it was not only the health and efficiency of the Army and Navy, but the morality of those towns which were heretofore protected, that was suffering to an alarming extent, owing to the withdrawal of the provision for compulsory examination; that, in fact, there were hundreds of young girls and women on the streets who dared not have carried on their trade had the Act been in force.

Mr. GLADSTONE said he was aware that the restrictions of the Act, whatever they were, operated upon the population of the places subject to the acts as well as on the troops who might constitute the garrison of these places; but if the assertion which the hon. member (Captain Price) conveyed in his opinion was correct, it appeared to him (Mr. Gladstone) that the police would have power to deal with such abuses as they arose. In answer to the noble lord, he had to say that he had consulted with his noble friend the Secretary of State for War, and he was of opinion, with his noble friend, that the time which had elapsed since the resolution against the compulsory provisions of the Act was adopted by the House did not disclose a state of things sufficient to warrant the Government in arriving at any positive conclusion, or in undertaking to announce any particular course of action. Out of a strength of 40,000 men there had been 27 additional admissions per week. Some part of the increase, however, might be explained by the circumstances surrounding the removal of troops to different places. He could not give an assurance that the same practice would have been adopted if the resolution had not been passed.

◆

The Irish Graduates' Association.—This Association held its annual meeting at the College, Shaw Street, Liverpool, on Wednesday, August 1, Prof. G. F. Yeo, M.D., in the chair. There was a good attendance of members. The Hon. Treasurer presented a favourable report. The Hon. Secs. presented the annual report. Prof. W. Stokes, M.D., was elected as President for the next year, when the meeting will be held at Belfast. A special vote, thanking the Vice-President (J. T. Banks, M.D.) for refusing the offer of knighthood which had recently been made to him, was passed with acclamation. In the evening the members and their guests dined at the Adelphi Hotel. The host provided an excellent dinner and wines, and the members entertained their guests with their usual hospitality. Dr. Strange, the President of the British Medical Association for last year, gave the toast of the evening, coupled with the name of Prof. Yeo, the President. The Hon. Sec. (Dr. Frazer) announced that he had received letters of apology from Dr. Waters, the late President, and Prof. Stokes, regretting their inability to attend.

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON.

[SECOND NOTICE.]

Though very many communications of great interest are contained in the remaining portion of the volume, we are compelled here to do no more than allude to them. There is, however, one feature which marks this volume, and which calls for more than a passing notice—we mean the discussion on Rickets with which it closes. The discussion occupied three nights, and was opened by Dr. C. H. Fagge. We notice the names of several of the leading physicians of London as taking part in the discussion, and as a result many points of great interest were stated; indeed, we may say that no part of the subject has been unnoticed. One of the first points discussed by Drs. D. B. Lees and Barlow is on "The Relationship of Craniotobes to Rickets and Congenital Syphilis." As bearing on this point we cannot but express our strong conviction that, through the entire discussion, quite too much importance has been given to the syphilitic poison as a cause of rickets affecting the bones of the skull. We do not believe this poison or its results to be at all as common as would be inferred from the discussion. One French writer, indeed, M. Parrot, goes so far as to set down to syphilis alone those changes in the skull which all other observers attribute to rickets. This is surely riding a hobby to death. For ourselves, we question whether these craniotobes can be the result of syphilis. If they be, the poison shows itself in what appears to us a most exceptional way. It does not declare itself for several months after the birth of the child; and then there is no sign whatever of rash on the skin, or breaking out about the mouth or anus, or snuffles, or loss of voice. Do not these symptoms, in 99 cases out of 100, appear in every syphilitic infant, and that within the first three months after birth? Or, should snuffles exist, and very many of the debaters seem to think these are *par excellence* signs of syphilis, may they not be rather attributed to the strumous diathesis? For ourselves, we hold that struma is an infinitely more widespread poison than that of syphilis; but the fashion of the day is to set down everything to the latter. We might instance the notching of the teeth, which seems to be accepted universally as the result of the syphilitic taint. We cannot accept this. We have seen over and over again instances where no trace of syphilis existed in either parent, and yet the notching was well marked; but, on the other hand, the signs of what are recognised as the strumous diathesis were very plain. Into these, however, we cannot enter here. The result of all our observation has been the conviction, as already stated, that struma is a tenfold more common poison than syphilis. The former shows itself under many modifications, and of these, rickets, we believe, to be one. This question of the greater prevalence of one morbid state over another seems to us one of great moment. We have stated our own views, but are very far indeed from supposing that the matter is settled. It strikes us that a prize offered for the purpose of deciding this question would be well spent.

The causes of rickets occupied, and naturally, much of the debate; but there would appear to be much diversity of opinion on the point. For ourselves, we hold with those who think improper food is the great factor in causing the disease. We consider that Guerin, to whose experiments Dr. Crisp alludes, has proved the fact beyond doubt. Nor does it follow that other causes besides food may not add to the severity of the disease. Thus, if in addition to improper food, impure air be added, the disease will be so much the worse, and the more rapid in its course. We think, too, that a weak constitution derived from either parent adds seriously to the chances of the disease appearing. We repeat, however, that Nature's food, which is the healthy milk of a healthy mother, will produce a healthy child, and that the farther any infant is reared from this standard the greater are the risks that rickets may ensue.

Into the morbid anatomy of the disease we cannot enter here. Several of the speakers alluded to it; but we are not sure that any of them gave a better account than Trousseau has done of the state of the bones, and we rather think his masterly description escaped their notice. As to the internal organs being involved, such as the liver, spleen, and mesenteric glands, it seems to us there is no absolute proof as yet that these changes are any necessary portion of the morbid anatomy of rickets. It may be admitted, indeed, that the state is sometimes found in union with rickets; but, as stated by several of the speakers, it is certain that the latter may exist to an extreme degree, and yet these internal organs be quite healthy; and on the other hand, the internal organs may be found diseased, without any other appreciable signs of rickets. We ourselves have seen the spleen so enlarged. We think it best, however, to consider the question as still *sub judice*.

To revert again for a moment to the etiology of rickets, we observe that one of the speakers alludes to the state of the blood in the disease as being very much deteriorated. For ourselves, we would look upon this as a *sine quâ non* of the affection. In other words, if the blood were in a healthy condition, we take it that rickets could not appear. And this idea may be pushed even farther, and we would put the question, Can the nervous structures be in a normal state and such a disease as rickets make its appearance? We think not; and we would make the suggestion that any future observer should turn his special attention to the state of the nerves and nervous structures in this affection. As far as we are aware, no one has hitherto done this; and yet the advancing knowledge of the day shows us what an all-important part healthy nerves have to say to a healthy frame; and *vice versâ*, what a number of diseases arise as a direct consequence of a diseased state of the nerves. Into this question, however, we cannot enter here, though we believe it to be one of the greatest consequence. Whether the nervous or circulatory system be the very beginning of life, we are not sure; but this we do know, that healthy life cannot continue without each being perfect in itself: and we again repeat that future inquirers into the proximate causes of rickets may gain an important step by ascertaining the state of the nervous system in this affection.

We commenced our remarks on the debate on this affection by stating that a debate of the kind was a comparatively new feature in the proceedings of the Society. We believe it, however, to be one well worthy of imitation, as it is certainly one capable of greater amplification than it has yet received.

In conclusion, we can recommend this entire volume to the special notice of our readers.

◆

THE INTERNATIONAL ENCYCLOPÆDIA OF SURGERY. (a)

The third volume of this Encyclopædia continues to exhibit the sustained excellence of its two predecessors, and contains 247 woodcuts and 2 chromolithographs. The articles are seven in number, and all upon subjects of importance and interest. Dr. P. S. Connor, of Cincinnati, contributes a splendid article upon diseases of muscles, tendons, and fasciæ, in which he maintains that muscular atrophy after fractures is due to reflex mal-nutrition, and not to disuse, in which all scientific pathologists will agree. Dr. Connor contributed in the last volume a most successful treatise on gunshot wounds, for which his experience during the Secession war so well qualified him. His present article is well up to the level of the former one. Dr. Lidell gives 300 pages upon injuries of the blood-vessels. Contrary to the general belief, he shows that the ligature was a very ancient mode of arresting hæmorrhage, and that it was known to Galen, Avicenna, and many of the old fathers of medicine. It is well known that Ambrose Paré introduced the ligature in amputations; but Dr. Lidell mentions that two centuries later Mr. Sharpe, Surgeon to Guy's Hospital, protested against the use of "burning irons," which were still employed in country parts of England. Dr. Wyeth is very happy in his account of the surgical diseases of the vascular system; and Mr. Barwell's article on Aneurism is interesting both to the physician and the surgeon. It is one of the best and most attractive retrospects of the subject that we have seen; and the same must be said of M. Nicaise's account of the diseases and injuries of nerves. M. Nicaise quotes extensively from the observations of Dr. Weir Mitchell during the Secession war. There are also very good articles on surgical diseases of the vascular system by Dr. John A. Wyeth; on injuries of joints, by Dr. Ed. Andrews; and on injuries and surgical diseases of the lymphatics, by Dr. Ed. Bellamy. This Encyclopædia so far is beyond all praise; it is all good.

HOSPITALS, INFIRMARIES, AND DISPENSARIES. (a)

Mr. Ruskin has taken general occasion to deprecate that canon of criticism which would raise the specialist in small fault-finding to the acme of the gay science, but the canon should vary with the end in view. The economist that would dwell on the constructive politics of M. Comte and pass over his profound analysis of social movement, or the resident physician that would snarl at Miss Nightingale's pardonable weakness on the relations of hospital management and nursing, and speak with little enthusiasm of her exhaustive treatment of training, would be alike unworthy of their tasks; but with matters that affect the sanitary construction of collective dwellings it is different. Here, there exists a more positive knowledge on what should be done than on what should not be done. An aggressive consensus of opinion that developed from the foreshadowings of Philibert Delorme into the organised maturity of the Tollet system has gradually swept the cobwebs from the minds of the custodians of public health, if not the hotbeds of pyæmia, erysipelas, and gangrene from our streets, but the recent failures of the Hotel Dieu and St. Thomas's Hospital, testify to the necessity of further strictures. It would thus seem a safer course to indicate the scanty defects than to indulge in a detailed panegyric on at least ninety per cent. of the works before us.

The first of these works suffers from a defect which in the second is removed by the joint names of its authors. The whole hospital question is so entangled with the profession of design as well as that of healing, that a signal success can nowhere be sought, but in their association. The present edition was preceded by two German ones in 1872 and 1875, and one English one in 1868, which was reviewed in the *Medical Press and Circular* of February 26 in the same year. It consists of two parts, the first being devoted to the evolution of principles, and the second to a description of their more or less successful application throughout the civilised world. Were the second part so occupied with the constructive details of those portions of hospitals which minister most directly to its hygienic maintenance, we could overlook the very meagre and often inaccurate notice granted them in the first part, but unfortunately this is not so. The descriptive division, though interesting and valuable, in that it deals with most of the hospitals in existence that are worth notice, is too categorical and confined. Drainage, of all theoretical questions, one of the most important to the hospital architect and engineer, is disposed of in one page. The question of the system to be employed for the removal of excreta, is not even touched upon, and this is the more reprehensible as it is still a matter for discussion, whether the water-carriage system is the best under all circumstances, or even to be employed at all. It is certain that many zymotic epidemics are due alone to this system, which even with the most approved design provides a possible *horizontal* communication from house to house. Admitting with Herr Oppert that this system is alone worthy of consideration, we doubt whether his version is calculated to display it to the best advantage. The following passage is a choice culmination :—

"The latest plan for ventilating drains is by having the vertical drains into which the pipes take the refuse from the water-closets and sinks open at the upper end, where a charcoal box with a perforated bottom is placed, or ventilating pipes are carried to the top of the chimneys."

A more involved tissue of error it would be difficult to select; of all the forms of insanity which have from time to time attacked the sanitarian, that which advocates drain ventilation by means of soil pipes is perhaps the worst. It has been amply proved by Sir Joseph Bazalgette that the drains are an inexhaustible source of foul air, and that even were an universal system of forced ventilation adopted, the amount of fuel required to furnish energy for the City of London alone would be comparable with the revenue. A charcoal ventilator on the top might, if newly charged once every month, be possibly able to filter some few per cent. of the foul blasts occasioned by a sudden shower or the casualties of a tidal outfall. Drain ventilation if permitted at all, should be confined to the central street manholes whose spiral charcoal or sulphurous acid disinfectors should be under some more constant inspection than that of the average householder. The drains are reservoirs of poison whose reducing power, within a considerable radius of an orifice is too enormous to be lightly dealt with. The most that can be done is to place safety valves upon this reservoir in such positions that the necessary and casual escapes may be reduced to a minimum as remote from human habitation as possible. Soil pipes, on the other hand, as presenting a very limited surface for organic decomposition should be continuously ventilated, not merely at one end, but at both ends, for whatever be the value of endosmose and exosmose as a means of draughtless comfort, something more brisk is required for the clearing of a soil pipe. Nor, again, should any ventilating pipe be carried to the top of a chimney; common sense would seem to indicate that the neighbourhood of any opening that may occasionally act as an induct is about the worst position for an educt. The subsequent statement that earthenware baths are the best is open to question as they are very heavy, liable to fracture, and have an inconvenient capacity for heat. Enamelled copper is unquestionably the best material and always brings a good price as old metal. With the exception of these and similar matters, which a comparison of Messrs. Mouat and Snell's volume will correct, Herr Oppert's work is a valuable one, which if a little too condensed is the more comprehensive. The articles on ventilation and the Continental system of hot ley washing are especially worthy of attention.

The second and more valuable work needs but little recommendation. Like Herr Oppert's it is divided into theoretical and practical portions, which are undertaken respectively by Messrs. Mouat and Snell. The first volume only is as yet issued, and in it the theoretical and part of the practical division appear. In the former some of the principles involved are more or less speculative in character, as the problems of life are scarcely as yet brought within the limits of exact science, but once a reasonable basis of certitude is established, the outward expression is reduced to a series of problems in applied science. Mr. Mouat dwells largely on that very little understood atmospheric state, *malaria nosocomiale*, the potent weapon of the anti-hospitalist. The alarming ravages of septicæmia in both the Schleswig-Holstein and the succeeding Austro-Prussian war cannot be overlooked, but so long as hospital air is practically capable of further liberation from putrefactive fermentation and germ development, we cannot yield in favour of either separate cells or out-door relief. Large hospitals under any circumstances are a grave error, and it may be proved both by calculation and experiment that the working expenses per head are not sensibly decreased in hospitals accommodating more than 200 sick. From such an aggregate, if disposed according to the thirteen conclusions of the Surgical Society of Paris, no baneful trace of the "nosocom-aër" need arise. The surgical operations in the hospital of St. Eloi at Montpellier from August, 1879, to June, 1880, though performed in the infancy of the building, were most encouraging, and although, as Mr. Mouat points out, the traumatic cases were very severe, all the operations were successful, there having been only a single death from cardiac embolism, eleven months after the admission of the case. This magnificent hospital, which is virtually a chain of small hospitals, would seem to embody in the author's opinion not only the conclusions of the Surgical Society of Paris, but also a number of practical excellencies which are due alone to its skilful architect and engineer, M. Tollet. Mr. Mouat's careful analysis of the claims of the several systems for the removal of excreta is attested by his adherence to each only so long as it seems the best suited to the conditions; to the water carriage system in cities, and to some one of the dry systems in the open country. His section concludes with a very careful classification of the various species of hospital, whose number, it is to be hoped, may gradually diminish now that their *raisons d'être* are to a great extent eliminated by the subdivision in the Tollet system. Mr. Mouat, though in favour of the complete separation of puerperal fever, and an extension of the proverbial nine days, is yet of opinion that the Rotunda Hospital in Dublin is one of the best-conducted and most efficient in existence.

The second and larger section, which is enriched by a number of clear photolithographic illustrations from the pen of Mr. Snell, contains a detailed examination of the most noted hospitals of various countries which have been erected since the introduction of the Pavilion system, interspersed with criticism and calculation that derive more than ordinary value from the widespread experience of the author. Of the foregoing works, that of Herr Oppert is useful from its compactness; but that of Messrs. Mouat and Snell is not only exhaustive to the smallest detail, but is compiled with that scientific acumen which the names of its authors should abundantly guarantee. No physician, surgeon, architect, engineer, or hospital governor should be without it.

THE POOR-LAW SUPERANNUATION (IRELAND) BILL.

The Committee stage of this Bill will be taken in the course of the present week, and if the measure gets past this step we have no doubt of its passing in the present year, as it is not likely to be modified by the House of Lords. We hear that the Government are disposed—as a compromise with the opposition of those of the Irish members who object to all discretion as to the grant of pensions being taken from the guardians—to amend the Bill so as to fix a minimum superannuation allowance, below which a board of guardians shall not go, but above which it shall have discretion up to a certain limit as to the amount which should be given. This proposition is very distasteful to us, because we are fully aware that there exists a class of guardians who would gladly use their discretion to spite the medical officer because he did not happen to be of their own religion or politics, or personally popular with them. But, considering that the session is dying—that many circumstances might arise before next meeting of the House to prevent the Bill being re-introduced if it were now allowed to drop, and that, in any case, the battle would have to be fought over again with the opposing faction—we see the necessity for accepting the Bill with this compromise rather than risk its being defeated or talked out. The discretion which it is proposed to give to the guardians is of much less importance to the medical officers than may appear at first sight, because the pensions are to be paid, not out of the rates of the union, but out of a general rate levied over the whole of Ireland, and retained by the Local Government Board for this purpose. Thus the guardians who have to vote a pension will not have to pay it out of their own pockets, and it may reasonably be presumed that they will —in most instances—be willing to tax other people in order to superannuate their own officers, and will, therefore, have no inducement to cut the pension down to the minimum.

It will be well for the Poor-law medical officers of Ireland to be able to recognise their friends in the future, especially when a general election is pending; we, therefore, give an abstract of the Irish names in the division list on the second reading of the Bill.

For the Bill—J. A. Blake, R. P. Blennerhassett, Maurice Brooks, G. Errington, W. Findlater, J. T. Hamilton, Col. King-Harman, Dr. Lyons, C. H. Meldon, W. H. O'Sullivan, A. M. Porter, T. D. Sullivan, Col. Tottenham.

Against the Bill—J. Barry, W. J. Corbet, C. Dawson, T. Harrington, T. M. Healy, M. J. Kenny, R. Lalor, J. Leahy, E. Leamy, J. M'Carthy, T. Mayne, B. C. Molloy, W. O'Brien, A. O'Connor, T. P. O'Connor, C. S. Parnell, T. Sexton, E. Sheil, J. F. Small, J. G. Biggar, J. O'Kelly.

KNIGHTHOOD FOR IRISH DOCTORS.

The irritation created by the recent offer of knighthoods to an Irish physician and surgeon, while baronetcies were being liberally dispensed in London, has been kept alive by the reply of Mr. Gladstone to the question put by Col. King-Harman, and by a very unnecessary and injudicious letter published in the Dublin papers by Mr. Wheeler, the President of the Irish College of Surgeons. Mr. Gladstone sought to explain away the transaction by the following extraordinary effort of sophistry:—

Well, I am informed, he said, that there is a separate medical profession in the three countries, and, viewed in that light, there has been recently conferred in England on two distinguished gentlemen baronetcies, and on one no less distinguished gentleman in Ireland there has been conferred a knighthood, and in Scotland there has been conferred no honour at all. A bill is now before the House to make the profession in the three countries one—one in standard and one in authority. We attach great importance to the views embodied in that bill, and acting on that principle we regard the medical profession as one. Of course I am very well aware that in advising the Crown in respect to questions of this kind I am liable to err, but I did not proceed on my own authority alone. I endeavoured to inform myself by a very full consultation with those who are known and regarded as the heads of the medical and surgical professions —not in any formal sense, but as probably leading persons in the profession, both medical and surgical—and it was after full consultation with them that I advised the Crown in its recent action. I am sure the hon. member has no intention to disparage the honour of knighthood, which I deem to be a very high honour. The title is one borne by the judges of the land and by the law officers of the Crown. A gentleman of very high position in the Irish medical profession has written to me stating that they regret very much that any notice indicative apparently of discontent should have been brought under my notice.

A less satisfactory explanation, in our opinion, could hardly have proceeded from the mouth of a minister, for Mr. Gladstone must well know, and he could not expect his audience to believe otherwise, that no matter how many attempts may be made to unify the profession, a distinction of nationality and of locality has always existed, and must always continue to exist, and that it was in recognition of that distinction that the recent decorations have been made to London and Dublin respectively. But it seems to us that the more the profession is regarded as one, the more the slight to Irish physicians and surgeons is intensified. If the knighthoods have not been offered to Ireland for geographical reasons, why has a difference been made between that country and England. Clearly the only other possible reason is that Irish surgeons and physicians are inferior in quality and only worthy of a lower recognition, and it is this inference that the profession in Ireland repudiate with such emphasis. Mr. Gladstone himself says that the Irish recipient of knighthood is "no less distinguished" than the London recipients of baronetcy; and we fail to see why an equality of attainments and position should not produce an equality of honour as indicated by Crown recognition.

Mr. Gladstone throws much of his responsibility upon those whom he consulted, or who amicably volunteered their advice, and he speaks of them as being "known and regarded as the heads of the medical and surgical professions." Being already aware that surgical distinctions in Ireland are usually given away on the sole and unsupported recommendation of a distinguished Court physician in London, we would feel better satisfied as to Mr. Gladstone's reasons for the course which he pursued if we knew whom he indicates as the "known and regarded heads of the profession." In the absence of that information, we must be content with declaring our belief that the "gentleman of very high position in the Irish medical profession" who took upon himself to pronounce that knighthood was quite good enough for Irish surgeons and physicians is certainly not "known or regarded" by any one, except himself, as a head of the profession, or he would have hesitated to obtrude upon the Prime Minister a secret prompting to the discredit of his own order.

A COMPLIMENTARY CRITICISM

Dr. Agnew, of Philadelphia, writes to the *Medical and Surgical Reporter* to state that he had received letters from various sections of the country asking for information in regard to his connection with a volume published by a Dr. Miller, and said to be by Drs. Stillé, Agnew, and Penrose. Dr. Agnew continues: "I have no relation whatever with this miserable piece of literary larceny, published entirely without my knowledge, and only remarkable for inaccuracy, stupidity, and audacity on the part of its author."

Pass Lists.

University of London.—The following is the Pass List in the Intermediate Examination in Medicine :—

First Division.

Adams, Charles Edward
Alcock, Samuel King
Barendt, Frank Hugh
Barratt, J. O. W., B.Sc.
Braddon, William Leonard
Carless, Albert
Corbin, Eustace Rhodes St. Clair
Dale, William Kelynack
Davenport, Arthur Frederick
De Chazal, Edmond Lucien
Gabriel, Leonard Maurice
Goodall, Edwin
Gow, William John
Gray, John Power William
Halstead, George E., B.A., B.Sc.
Hart-Smith, Frank Chamberlain
Hichens, Frank
Hutton, John Stuart
Johnson, Raymond
Jones, Sydney Harold
Kidd, Hugh Cameron
Larkin, Frederic Charles
Lever, Frederick
Melson, George Hyde
Price, Alfred Edward
Stedman, Frederick Osmund
Stevenson, George
Thane, Edgar Herbert
Washbourn, John Wychenford
Wild, Robert Briggs
Wills, William Alfred

Second Division.

Aikin, William Arthur
Bailey, William Henry
Barwise, Sidney
Bright, Eustace Frederick
Calvert, James, B.A.
Childe, Letterstedt Frederick
Clegg, Joseph
Edge, Frederick
Finley, Frederick Gault
Gardner, Henry Willoughby
Goodall, Edward Wilberforce
Harsant, Joseph George
Heatherley, Francis
Lawson, Robert
Leech, Priestley
Marriott, John
Morison, Frederick William
Mourilyan, Edward Pain
Muspratt, Charles Drummond
Napier, Francis Horatio
O'Brien, Patrick Moriarty
Pailthorpe, Mary Elizabeth
Prall, Samuel Esmond
Sutton, Alfred Martin
Thomas, Benjamin Wilfred
Walker, Alfred William Hinsley
Wethered, Frank Joseph
Williams, Patrick Watson

Excluding Physiology. First Division.—Wynter, Walter Essex. Second Division.—Ackland, Charles Kingsley; Roberts, Edward; Taylor, Charles Henry; Williams, Reginald Muzio.

Physiology only. First Division.—Freeland, Freeland John. Second Division.—Carpenter, George Alfred; Lankester, Alfred Owen; Marriner, William Herbert Lister.

University of Edinburgh.—At the graduation ceremony on Wednesday, August 1st, the degree of Doctor of Medicine was conferred on the following candidates :—

Allan, Francis John, Scotland, M.B. and C.M., 1880.
*Ashdown, George William Wetton, England, M.B. and C.M.
*Bain, David Beattie, Scotland, M.B. and C.M., 1872.
***Balfour, Isaac Bayley (D.Sc. Edin.), Scotland, M.B. and C.M., 1877.
***Barbour, Alexander Hugh F. (M.A. Edin.), Scotland, B.Sc., M.B.
Baxter, William, Scotland, M.B. and C.M., 1877.
*Berry, John Bright, England, M.B. and C.M., 1880.
Blaikie, Robert Henry (M.A. Edin.), Scotland, M.B. and C.M., 1881.
Cameron, John, Scotland, M.B. and C.M., 1877.
*Craig, James, Scotland, M.B. and C.M., 1872.
Firth, Eustace, England, M.B. and C.M., 1880.
**Fraser, Frederick William Dyce (M.A. Edin.), Scotland, M.B. and C.M., 1878.
***Fraser, James William, England, M.B. and C.M., 1880.
Hartley, Alfred, England, M.B. and C.M., 1881.
***Hassall, John, England, M.B. and C.M., 1876.
*Hern, John, England, M.B., 1881.
*Illingworth, Charles Rumney, England, M.B. and C.M., 1877.
Johnston, Robert M'Kenzie, Scotland, M.B. and C.M., 1881.
Kay, Walter Smith, Scotland, M.B. and C.M., 1877.
Lewis, Thomas Preston, England, M.B. and C.M., 1877.
*M'Dowall, John Grieg, Scotland, M.B. and C.M., 1878.
Reid, George More, Scotland (under the Old Statute).
*Retief, Petrus Jacobus, Cape of Good Hope, M.B. and C.M., 1880.
*Robertson, Alexander Milne, Scotland, M.B. and C.M., 1872.
*Robertson, James George, Africa, M.B. and C.M., 1876.
*Rose, Alexander Simpson, M.B. and C.M., 1880.
Smith, Thomas Henry, England, M.B. and C.M., 1880.
*Watkins, Arnold Hirst, England, M.B. and C.M., 1875.
*Waugh, John (M.A. Edin.), Scotland, M.B. and C.M., 1881.
Weight, Rowland Hill, England, M.B. and C.M., 1880.
Wortabet, Henry George Luther, Syria, M.B. and C.M., 1878.

*** Obtained Prizes for their Dissertations.
** Deemed worthy of competing for the Dissertation Prizes.
* Commended for their Dissertations.

At the same ceremonial the degrees of Bachelor of Medicine and Master in Surgery were conferred on the following candidates :—

Addinsell, Augustus W., England
Aikman, Alfred, Scotland
Aitken, Charles, India
* Alexander, George F., Scotland
Baily, Edwin, England
† Baily, Percy John, England
Ballantyne, John W., Scotland
Bancroft, Thomas Lane, England
† Barker, Theodore H., Australia
Barrett, William H., Gibraltar
Barron, Hunter J., England
Bennet, D.G.(B.A. New Brunswick)
Bett, Patrick Hunter, Scotland
Bird, William, England
Bowes, John, Scotland
Broatch, George Thomas, Scotland
Brown, Charles, Scotland
Brown, John Henry, England
Buist, Andrew Crichton, Scotland
Buncle, Thomas M., Scotland
Cardew, George Schuyler, India
Caw, James Matthew, Scotland
Chill, Edwin Albert, India
Clark, Michael, England
Clark, Ronald, Scotland
Clemow, Arthur H. W., England
Cobbett, Charles N., England
Cockburn, Philip, Scotland
Cocks, Horace, England
Comber, Sidney Alfred, England
Connor, Francis Gillies, Australia
Cotton, William (M.A.), Scotland
Craig, James, Scotland
† Cumming, William, Scotland
Dalgleish, James, Scotland
Dalziel, Thomas Kennedy, Scotland
Davies, Daniel Rees, England
Davies, John, Wales
Davies, William Hugo, England
Davison, Thomas H., England
† Dochard, Archibald T., Scotland
† Donald, A. (M.A. Edin.), Scotland
Dring, Herbert Johnson, England
Drummond, Alexander P., Scotland
† Duff, William, Scotland
Duncan, George, Scotland
Dyson, Thos. Edward, England
Evans, David Griffith, Anglesey
Fletcher, Thomas J., England
Fordyce, Boston E., Scotland
Francis, William Henry, Chili
Fraser, A. G. (M.A. Aber.), Scotland
Fraser, William Duncan, Wales
† Fuller, Arthur, England
Gardiner, M. H. (M.A. Glas.), Scotland.
Garman, Walter C., England
Giddings, Robert Ritchie, England
† Godfrey, Frank W. A., Australia
Gordon, Robert, England
Gowans, William Bruce, Scotland
Greenhough, V. J. (B.A. Cantab.), England
† Grierson, Francis W., Scotland
Gutteridge, Matthew W., England
Hall, Francis James, England
Hall, Frederick W. George, India

* Passed with First-class Honours. † With Second-class Honours.

Army Medical Service.—The following is the list of the candidates for appointments as Surgeons who were successful at the competitive examination recently held at Netley :—

	Marks.		Marks.
*Bruce, D.	2975	Moore, R. R. H. ..	2000
Gordon, H. C... ..	2320	O Shaughnessy, P. J. B.	1455
Bell, H. L.	2186	Robertson, J. R. S. ..	1965
Riordan, J.	2285	Tate, A. E.	2050
De Lom, H. A... ..	2101	Faunce, C. E... ..	1792
Firth, R. H.	2460	Lendrum, W. H. ..	2200
Nelis, G.	1990	Wyatt, H. J.	1613
Gallwey, P. J... ..	1699		

* Gained the Montefiore Second Prize.

Indian Medical Service.—The following is the list of the candidates for appointments in this Service who were successful at both the London and Netley examinations recently held :—

	Marks.		Marks.
†Young, J. M.	5680	Quicke, W. H. ..	4733
Jameson, G.	5257	Evans, A. O.	4691
Collie, M. A. T. ..	5225		

† Gained the Herbert Prize, Martin Memorial Gold Medal, Montefiore Medal, and Parkes Memorial Bronze Medal.

◆

Notices to Correspondents.

The Students' Number, 1883-84.—The annual educational number of this Journal will be published on Wednesday, September 19th. Deans, Registrars, and others connected with the various medical schools throughout the United Kingdom, will oblige by forwarding the latest prospectus and such other information as will assist the Editors in the compilation of this important number.

THE COST OF PAUPERS.

From a Parliamentary return just issued relating to poor-rates and pauperism, it appears that the total expenditure for relief of the poor, during the half-year ended Lady Day last was, £2,252,286. Of this sum £982,586 was for in-maintenance, and £1,269,700 for out-door relief. The return comprised 647 unions, and a population of 25,972,119.

Mr. A. P. P.—We consider that, assuming your version to be strictly correct, your associate has not acted up to his engagement, and if persisted in, should be a sufficient legal reason for you to cancel the partnership. Probably, however, friendly counsels would bring him to see matters in a different light.

Sclerosis.—Messrs. Krohne & Sesemann, of Duke Street, Manchester Square, W., are the makers of the instrument. Send for their catalogue; we do not know the price of instrument.

Just Passed.—There are no more appointments open; the gentlemen sent to Egypt were specially selected for their fitness and knowledge of the subject. It is true one of the number, Mr. Theodore Acland, only passed the College of Physicians the day before his departure, but this was the only exception, and was probably due to the exercise of a little private influence. Without this we fear you would stand but little chance of being selected, as there were many applications from those who had been long qualified.

Mr. J. A. B.—The father of the person referred to was a notorious quack, *soi-disant* Professor B——. After he had been convicted of falsely styling himself "Doctor," to avoid this *contretemps* happening to his son, he educated him as a surgeon, and he now holds the M.R.C.S. Eng., and practises the arts of quackery with his father under this legal protection.

Mr. R. F. Bennett.—You will find your inquiries fully answered in Dr. von Pettenkofer's work on Cholera, published by Messrs. Baillière, Tindall, & Cox, 20 King William Street, Strand. Treatment by injection of saline fluid was successfully resorted to as long as thirty years ago.

F. F. B.—The official Pharmacopœia does not include a large number of new remedies which have been adopted into general use. The revision it is now undergoing will result, probably, in the more important of these finding a place as officially recognised therapeutical agents.

M.B., M.A.—You should address your application to one of the local secretaries at Liverpool; it will certainly be attended to, but we cannot undertake to say your suggestions will be adopted.

Dr. Carter.—The subject is referred to in our present issue. The information was forwarded by the gentleman who is most interested in the matter, and to whom you might very properly address yourself.

Inquirer.—The publishers of Foster's "Embryology" are Messrs. Macmillan & Co.

WHAT ARE THE PREDISPOSING CAUSES OF CHOLERA?

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—For many years I have been the physician and surgeon of the Ballingarry dispensary district, in the Callan Union. I well recollect conversing with its various inhabitants on the subject of cholera, and was then told by some of its inhabitants residing in the village of Ballingarry, that when the cholera was present there, that one-half of the street was attacked with cholera, and that the remaining half was perfectly free. This I do know for a fact, that one side of the aforesaid street had a sewer running parallel with the aforesaid houses in the rear, and at a very short distance from the said houses. As to the side opposite, I have now no recollection of the matter.

21 Richmond Hill, Rathmines, Dublin,
August 8th, 1883.

Yours, &c.,
Geo. Rowles.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopædic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.

TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's, 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 3 p.m.

WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopædic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m., and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Vacancies.

Cashel Union, Cashel Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, September 1st.

General Infirmary, Gloucester.—House Surgeon. Salary, £100, with board. Applications to the Secretary before September 1.

Gloucester County Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to the Medical Superintendent at Wotton, on or before August 20.

London Hospital.—Demonstrator of Practical Chemistry. Salary, £100, and a proportion of fees. Applications to the Warden before September 1.

North Wales Co. Lunatic Asylum, Denbigh.—Assistant Medical Officer. Salary commencing at £100, with board. Applications before August 1ᴴ.

Thomastown Union, Graigue Dispensary.—Medical Officer. Salary £100, and fees. Election, August 23.

Ulverstone Union.—Medical Officer of Health for the Rural Sanitary Authority. Salary, £133. Sealed applications to the Clerk before August 22nd.

Appointments.

Hunter, J., F.R.C.S. Ed., Lecturer on Animal Physiology to the Watt Institution, Edinburgh.

Lane, J. L., Assistant Physician to the Rotunda Hospital, Dublin.

Lyons, A. de C., M.B., M.C. Aber., Public Vaccinator to the Yatton District of the Bedminster Union.

Mellor, T., M.R.C.S., Medical Officer to the Workhouse of the Bury Union.

Moore, E. E., M.B., Resident Medical Assistant to Down District Lunatic Asylum.

Nisbett, R. I., M.R.C.S., Consulting Surgeon to the Gravesend and Milton Infirmary and Dispensary.

Oulton, H. W., Medical Officer to No. 1 North City Dispensary, Dublin.

Stafford, T. J., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the No. 1 Dispensary District of the Boyle Union.

Steel, W. D., M.D., Medical Officer of Health to the Abergavenny Union District; also Medical Officer to the Abergavenny Union, and to the Ulanarth District.

Treves, E., M.R.C.S., Assistant Surgeon to the Brighton, Hove, and Sussex Throat and Ear Dispensary.

Births.

Anderson.—August 8, at Spennymoor, Durham, the wife of Robert S. Anderson, M.B., of a son.

Chitty.—August 3, at Crouch End, the wife of A. Goldney Chitty, M.R.C.S., L.R.C.P., of a daughter.

Embleton.—August 8, at 25 Park Crescent, London, the wife of D. C. Embleton, M.R.C.S., L.R.C.P., of a daughter.

Graham.—August 2, in Sumatra, the wife of J. Campbell, M.D., M.A., L.R.C.P. Ed., of a daughter. (By telegram.)

Grimshaw.—August 8, at Priorsland, Carrickmines, co. Dublin, the wife of Thomas W. Grimshaw, M.D., of a daughter.

Deaths.

Axford.—August 8, at Sunnyside, Bath, after a lingering illness, Richard Axford, M.R.C.S., J.P., late of Bridgwater, aged 64.

Carter.—August 9, at his residence, Kilcullen, co. Kildare, Robert Cook Carter, M.D., aged 77.

Martin.—August 1, at Ellangowan, South Norwood, Anne Stuart, wife of Surg.-Major James Martin, A.M.D., aged 54.

Southam.—August 2, at Thorne Road, Peterborough, Thos. Southam, M.R.C.S., L.S.A. Lond., aged 74.

ON SOME FORMS OF DILATATION OF THE COLON, SPECIALLY IN REFERENCE TO THE DIAGNOSIS OF THE AFFECTION. (a)

By HENRY KENNEDY, A.B. M.B. T.C.D.,

Fellow of the King and Queen's College of Physicians; Physician to Simpson's and the Whitworth, Drumcondra, and formerly attached to the Cork Street Hospital, and Sir P. Dun's.

It will be admitted that, within the last 25 years, great advances have been made in our knowledge of all the organs concerned in the process of digestion. The much greater care which is now bestowed on the minute anatomy of each portion of the intestinal tract, together with the increased knowledge of the morbid anatomy, and above all the advances made by physiology, including the knowledge we now have of the various peptic ferments, these, one and all, have powerfully tended to enlarge our experience, and give us clearer ideas on the subject generally. On the other hand it must be also admitted that a vast deal yet remains to be cleared up before we can be said to have approached to that end so much to be desired. I used the word "approached" advisedly; because, I believe, we can never reach to certainty either in this or any other branch of medicine. The nature of the subject does not allow it. We must, however, do our best to overcome the difficulties which exist, and I do not know any better plan than to take up some special point for discussion, and with this idea, I have, on this occasion, selected the subject of dilatation of the colon as being one worthy of notice. In any remarks I shall make on this subject I shall not speak of the cæcum, as its consideration would far exceed the limits of a paper such as I now have the honour of presenting, neither will it be possible to do more than make a very few general remarks, which will, however, help to introduce the more immediate subject of the paper.

Into the several points connected with the colon which must strike anyone, on the most superficial views of the subject I need not here speak at length. Its size, its relative position, its numerous sympathies, its functions, its peculiar anatomy, relatively to both the arrangement of its muscular fibres, and the minute anatomy of its mucous membrane, are known to all; but should any of my hearers wish to be better informed on the subject, and in a clinical point of view, I would refer them to a brief but admirably written paper by the late Sir Henry Holland, who scarcely touched anything in his valuable essays that he did not adorn. Neither of the diseases of the colon would it be possible to speak here at length. It is certain, however, that they are both numerous and important. My own conviction is that they are both more numerous and more important than those of the ileum, which has had so much attention bestowed on it, owing to its being the chief seat of the lesions of typhoid fever. We must not forget, however, how often the colon shares in this state, and on another occasion I have called attention to this special point, and have shown that the greater amount of disease may be found in the colon. I see too, cases lately given where typhoid fever has led to perforation through the colon, just as occurs in the ileum. There will be occasion to allude to this point further on. But the state of the colon to which I wish now more particularly to ask your attention is that of dilatation of the organ; nor am I aware that, in the aspect in which I would speak of it, has it been described by any author. That the colon acts as a reservoir for the fæces is certain; and that owing to this function it is capable of being dilated beyond its normal size is well known. But I would wish to go further, and to recognise the fact that dilatation of this portion of the intestinal tube may exist without there being any apparently mechanical cause to have led to it. To say that an accumulation of the fæces never existed in such cases at any period would be going further than facts would justify; and the chief function which has just been alluded to, that of a reservoir, must afford a strong presumption, at least, that it was owing to an abnormal accumulation of the fæces dilatation ensued. I may say, however, that I have met cases where there was no history of previous constipation which would account for the dilatation present. (*a*) That this state of the intestine is of more frequent occurrence than is commonly supposed I cannot doubt, and that it gives rise to a number of troubles is certain. We all know what numerous symptoms, serious and otherwise, arise from simple constipation. To attempt to describe them would here be quite out of place. Suffice it to say they may affect the head, chest, or abdomen; or the general health may be most seriously impaired, or melancholia may exist, for I believe one of the main causes of that most distressing and obstinate complaint often has its origin in one or other form of derangement of the colon. As bearing on this point too I need not remind you of the fact that malposition of the colon is by no means unfrequently met with in cases of insanity. You all know that in such cases the transverse colon dips down towards the pelvis, so as to form a concavity upwards. This state I believe I have diagnosed during life, but I would speak with reserve on this point. It seems clear, however, that when it does exist it must necessarily interfere, in a degree, with the natural functions of the part.

(a) Verbatim report as read before the Medical Section, Academy of Medicine in Ireland, May 18, 1883.

If it be assumed then that constipation is the starting point of dilatation of the colon it is easy to understand how this state will become a permanent one; for the over-distension must lead in time to injury, more or less, to the muscular coat, which we know to be so peculiarly developed and, placed in this intestine. The process may be, and indeed necessarily must be slow, and it stands out in this respect, as a contrast to what occurs in the urinary bladder, where a few hours of over-distension is frequently followed by serious injury to the muscular power of the organ. Still, in the colon if the process be slow it is sure, and it is more than probable that the muscular coat must degenerate into the fatty state; in conformity with the well known law that when muscle is not exercised it surely degenerates.

These two causes, then, that is over-distention and change in the muscular texture, seem quite capable of accounting for the state of the colon of which I am speaking. To these some might be inclined to add the peculiar anatomy of the part itself; its puckered appearance, and its division into cells, inviting, as it were, to constipation, and so to dilatation. At any rate whatever be the cause or causes of this state, certain it is that it often exists, and so constitutes a diseased condition. Now the diagnosis of dilatation of the colon, simple though it may appear, is not by any means so easy as might be thought, and indeed, there is no doubt that it is often overlooked, if not quite mistaken. I suppose I address few who have not known instances of this sort; where very serious mistakes have been made, and impacted fæces have been supposed to be other and grave diseases. To accoucheur,s in particular, such cases are of frequent occurrence; nor need I revert to them more than to say tumours formed in the colon are capable of being mistaken for uterine and ovarian tumours. The following case is sufficiently obscure to be introduced here:—

Case I.—A lady close to 60 years, a widow, but without family, has been under my observation for about five years. The patient has four distinct tumours in the abdomen, which when handled convey the idea that they are floating about, for they can each be moved a little. The largest is the size of an orange, and the others a little smaller. One is close to the uterus, but a little to the left side. The curious feature of this case is that these tumours have existed for the long period of twenty-five years, and as far as I can learn little, if any change has taken place in them, nor did they give the patient any annoyance. About two years ago she was seized with a very severe hæmorrhage from the kidneys, and lost so large a quantity of blood as to have been completely blanched. Some of the blood which came away literally coagulated, and it did not seem to affect the tumours in any way. The patient, whilst at the worst, showed a very peculiar state of mind, which I set down to the peculiar loss of blood, and which passed away as she grew better, and she has had no return since. (*a*) Dr. Denham saw the case with me. The diagnosis of this case I leave to others, for I must confess myself unable to make it. The case, however, is I think, worthy of being put on record. It should have been stated there is nothing apparently wrong with the uterus itself, nor has the patient any marked trouble with the bowels. A case of a somewhat different character is the following. (*b*)

Case II.—The patient was a maiden lady of middle age, spare habit, and sedentary life. Her abdomen became gradually and almost imperceptibly swollen, and no inconvenience was experienced, except a tendency to constipation. The bowels, however, yielded to ordinary purgatives, but such evacuations were not followed by any subsidence of the tumefaction. At the post-mortem examination the entire colon was found enormously dilated, and its coats thickened; but only the sigmoid flexure is preserved in the Museum of the College of Surgeons, and it when stuffed and dried is about four feet long, and two in circumference. It is significantly added that the nature of the affection was not guessed at during life, and to this statement is appended the respected name of the late Mr. Cusack.

Case III.—A girl, æt. 17, began to get out of health in December, 1879, but she had no definite symptoms, nor pain. In January, 1880, the bowels became irregular, at times there was constipation, and again diarrhœa, and with this state the abdomen began to change, and when admitted in Guy's Hospital in August, 1880, that is to say, about ten months from the time her health had first failed, the abdomen had attained a great size, and severe diarrhœa existed, the discharges being offensive and dark coloured; but still no pain on pressure or otherwise. When admitted she was so anæmic as to suggest the idea that she had been losing blood. Her expression was anxious and her pulse rapid. It is enough to say of this case that she lived about a week after her admission, having been seized at the last with pain in the abdomen, which rapidly increased in severity, was attended with collapse, and then death. On examination it was found that the colon, commencing at the hepatic flexure, was much dilated, the hepatic flexure measuring eleven inches, the sigmoid thirteen inches, and the rectum seventeen inches. The coats of the bowels were somewhat hypertrophied and hard to the touch, and in the rectum were found some superficial ulcers, two of which were each the size of half-a-crown; whilst in the sigmoid flexure a large one with sinuous margins existed, in the centre of which perforation, leading to a fatal peritonitis, was found. Though a large quantity of black pultaceous fæces was in the colon there were no scybalæ. All the other organs in both abdomen and chest were healthy. Dr. Goodhart, the gentleman who details this very interesting case (Clinical Society's "Transactions," vol. xiv.), might well speak of it being rare. He avows that he considered it to have been a case of tabes mesenterica, nor did anything occur during the life of the patient to alter this view, and it was only the post-mortem examination which showed the real nature of the case. But there is not time to enter here into the special points which this patient exhibited. The three cases which have been just sketched are, I consider, sufficient to illustrate some of the difficulties which belong to the subject brought under notice. They could have been very easily added to, but even in themselves they prove to demonstration the mistakes which may be made in the diagnosis, and, as already stated, it is to this special point, I mean the diagnosis, that I would now ask attention.

Can the diagnosis, then, of dilatation of the colon be

(*a*) Other parts such as the œsophagus, stomach, heart, &c., exhibit dilatation without any very obvious cause, and it is more than probable the colon may take on a similar diseased action.

(*a*) I have seen some cases of mental disturbance exactly similar, which occurred after severe fevers.

(*b*) Some years since Dr. Shannon kindly showed me some very interesting cases like the one given above.

made out during life? I believe it can, and by a series of symptoms which it is scarcely possible to overlook. But then attention must be drawn, in the first instance, to the possibility of making the diagnosis, and I do not find in any of the standard works with which I am acquainted that any such attempt has been made. Hence, the first idea is as to making the diagnosis at all, and, keeping this point in view, to proceed then to detail the symptoms. And here I would wish it to be understood that I am not now about to speak of cases where fæcal accumulations could be felt during life. These may have existed at some former period, as I have already stated, but in what I am now about to describe I do not contemplate such a state of things. What, then, are the symptoms which dilated colon cause? In the first place, the parties are always more or less invalids. They may get through their ordinary business, but few days elapse in which they have not one or other complaint referred either to the head, chest, or abdomen. The appetite is fickle, their food not being enjoyed, but their bowels seem to be quite regular, and in some of the cases I have seen, the parties have two evacuations every twenty-four hours. When such a comparatively rare thing as this occurs it should always attract our attention, for it is certainly exceptional, and has some specific cause. When I first met it I thought it might be accounted for by the parties being very hearty eaters, but a more enlarged experience showed me this could not be the cause, as I found it existed when the appetite was quite moderate, and I am now inclined to think it is most likely due to the state of the bowel, which, from its greatly increased surface, must necessarily pour out far more excretions than it would in a state of health, and so make the bowels act more than ordinarily. This idea will, I think, be borne out more fully as I proceed.

When we come to examine a patient whose colon is dilated as he lies on his back, we are at once struck with the fact that the abdomen is somewhat larger than natural, and percussion elicits a clear sound; and this is the more marked the thinner the patient is, and, speaking generally of them, they are thin. No pain is complained of on pressure, but in some instances pain which seems to arise from the displacement of flatus is felt. But it is in the character of the evacuation from the bowel that the chief characteristic of the disease is seen. It may be said once for all that the fæces are never healthy, and this is a sign which, if looked for, cannot be mistaken. Besides being discoloured, the fæces are always pasty and unformed, and invariably sink to the bottom of the pan. The quantity may be, and often is, large, but it has always the characters mentioned, and no means I have yet tried have altered them. In confirmation of the remarks just made, I shall give a brief sketch of two cases at present under my care.

Case IV.—A gentleman, about 50, has been my patient for several years. He has been an asthmatic, but never to a violent degree. Within the last four years he has begun to complain very much of his head, and has had very severe attacks of giddiness which were twice attended with some vomiting. He always had the habit of coming to my house till the occasion of one of these attacks, when I saw him at his own home, and then for the first time discovered the nature of the discharges from his bowels. They were darkish, pasty, and unformed, and I have never succeeded in rendering them better, though I have tried a good many remedies; amongst the rest, he has visited Harrogate. This patient bears mercury very badly. He now complains so often that he must be considered a confirmed invalid, even though he struggles to carry on his business.

Case V.—A gentleman, close to 60, applied to me for advice about two years since. He described a number of symptoms, referred chiefly to the left side of the body, and which were more like those of hysteria than anything else. The attacks in this instance are described as commencing in the abdomen, and spreading both up to the side of the neck and down the limbs, especially the left one. When he pleases he can, by a particular movement, cause a very peculiar sound in the abdomen, like the gurgling of fluid in a large cavity. Though a thin man, his abdomen is larger than what is natural, and tympanitic, but the closest examination does not detect any tumour. The discharges are precisely similar to those last described, being dark, pasty, and unformed. But there are more signs of irritation of the mucous membrane in this instance than in the last case. Thus, the patient has an inclination to a motion every morning before he gets up, to which he must attend, but if the call be not attended to, or not so urgent as usual, he finds it scarcely possible to get the bowels to act through that day. Since I have been seeing him he has had one rather sharp attack of diarrhœa. This gentlemen has been seen and treated by different medical gentlemen. What views have been held about the case I do not know, but that he has a dilated colon I cannot doubt. Treatment has benefited him, though he is far from being cured.

The cases given are, I think, quite sufficient to prove that not only dilatation of the large bowel exists—a fact long known, but that its diagnosis can be absolutely made out—a point which, as far as I know, has not yet been attempted. Nor let it be supposed that this last point is one of little moment. At first the impression would be that it was of no great importance. But I cannot look upon it in this aspect, for even in the very mildest form of the disease—that is, when the colon is dilated by impacted fæces—it entails a chronic state of broken health; whilst in the form to which I would more particularly ask attention—that is, dilatation without any impaction of fæces, or tumours to be felt through the abdominal walls—I look upon the affection as very serious. Nor, indeed, when we consider the state of the parts, can this seem strange, for the mucous membranes, now so much enlarged, cannot be in a healthy condition, and is constantly pouring out unhealthy secretions which in their turn lead to ulceration, and this again to perforation. I have already alluded to the fact that perforation has occurred in typhoid fever, and in addition I find quite a number of cases—more, indeed, than I had any idea of—detailed in which this accident had occurred. One case I saw myself, but unfortunately I am only able to say of it that it occurred in a shoemaker, 55 years of age, who was suddenly attacked with severe pain in the left side of the abdomen, followed by collapse and death, after about thirty hours' duration. I was asked to assist at the post-mortem examination and we found all the marks of peritonitis, of a limited character, however, in the left side of the abdomen, and this had arisen from perforation of an ulcer of the sigmoid flexure of the colon. Besides this danger, however, the patient is very liable to attacks of diarrhœa, which may run into dysentery, or become chronic, and I have observed that they are subject at times to a sudden deterioration of the general health, which it is hard to relieve, and during which we must not forget that ulceration may occur. The presence, indeed, of ulcers is a point we should ever keep in view in these cases; they may be singularly latent as regards any symptoms to which they give rise, and post-mortem examination may be the first notice we get of their presence.

For these reasons, then, I look upon the affection I have attempted to describe as very serious, and our prognosis should be in keeping with such views.

As to treatment, I wish I could add anything that could be thought worthy of notice. But I am unable to do so, and can only say that every measure, general and medicinal, which can possibly raise the health of the patient is to be carried out. The diet, of course, must be strictly regulated. Of medicine I think I may recommend one or other form of strychnine, or this combined with iron, but astringents, as a class, are to be avoided.

In conclusion, I will throw into propositions the several points which I wish to bring more particularly under notice:—

1. That dilatation of the colon, whether caused by impacted fæces or otherwise, is of frequent occurrence.
2. That this state is always accompanied by impaired health, and may give rise to symptoms referred to the head, chest, abdomen, &c.
3. That it is a state which may be readily overlooked, as some of the cases detailed this evening clearly prove.
4. That, nevertheless, the diagnosis can be made during life.
5. That the diagnosis turns on the presence of chronic tympanitis, usually slight in character, together with fæcal discharges which never are normal, and are one or more in the twenty-four hours.
6. That diarrhœa, acute or chronic, or dysentery, are common attendants on dilated colon.
7. That this state of the colon is frequently attended by ulceration on the mucous surface, which has led in many instances to perforation of the bowel and death.
8. That the prognosis should ever be most guarded.
9. That treatment may afford marked relief, and so prolong life, but that a complete cure can scarcely be expected.

◆

PEPTONISED FOOD.

By PROSSER JAMES, M.D., M.R.C.P. Lond., &c.,

Lecturer on Materia Medica and Therapeutics at the London Hospital; Physician to the Hospital for Diseases of the Throat and Chest.

We are constantly liable to meet with cases in which the chief, sometimes the only, difficulty is to introduce nutriment into the system. Even when it is not necessary to resort to rectal alimentation, it is often nearly impossible to induce the patient to take food. All kinds of suitable dishes are successively prepared, tasted and refused. Milk in all forms may be rejected. When peptonised, this fluid is most easily assimilated; but the process needs a little care. If carried too far, the bitter flavour developed is apt to set the patient against it. Beef-tea—the sheet anchor of so many—is very variable in quality. Every cook and every nurse professes to make a perfect article; but too often the fluid presented under the name of beef-tea is anything but appetising. Extract of beef is often added, but its defects are well known. In France the juice of underdone beef is forced out by a powerful process, and considered more nutritious than our beef-tea. I have known one case where nothing else was taken for many weeks. The plan of peptonising food seems to be a distinct advance in dietetic therapeutics.

Lately, as a substitute for beef-tea, I have been trying "Carnrick's Beef Peptonoids," a preparation which possesses the convenience of being always ready. It seems to be a powdered extract of beef, which has been partially peptonised, and then mixed with an equal weight of gluten. The object of this admixture is to overcome the tendency to deliquesce, and so permit the preparation to be kept as a dry powder. Gluten, being itself highly nutritious, seems a suitable substance for the purpose. For rectal alimentation this powder has been largely employed. In the case of the late President Garfield, the peptonised extract was prepared by the same firm in a fluid form, and seems to have given full satisfaction to the physicians in attendance. This led to the attempt to produce a preparation which would keep; and the powder is the result of the experiments made with that view. Mixed with hot water, a nutritious fluid is at once ready, to which may be added such other food or medicine as may seem requisite.

It is, however, chiefly as a substitute for ordinary beef-tea, to take by the stomach, that I would direct attention to it. Firstly, as to taste. Some patients will object to it, but I have found some prefer it to their ordinary beef-tea; and, of course, flavouring ingredients may be added if desirable. The powder may further be employed to strengthen ordinary beef-tea or soups. But when the patient is being fed on milk and beef-tea only, and can take but a little at a time, the convenience of such a preparation is most obvious. I have given it alternately with milk every two or three hours, day and night, and the patient has declared it more supporting than anything. One patient preferred it to the beef-tea made by three different cooks. Others like to use it to strengthen the produce of their kitchen.

In the following case the preparation was in constant use for weeks:—

A. B., a widow, æt. 80, took cold in March last. In a few days loud râles spread all over the chest, back and front; there was great dyspnœa, loss of appetite, and depression. On the 22nd, a new night nurse was installed, and directions given, above everything, to keep up the feeding. The patient could not lie down; the wheezing was loud; the râles universal. Pulse, 120; respiration, 36. She could only speak in a whisper, one syllable at a time. Beef-tea, milk, &c., to be given in small quantities as often as the patient could take them. Ammonia and ether were also given. The same state continued, but more aversion for food was manifested; and on the 26th, peptonised milk and peptonised jellies were began. These were taken for four days, when the patient refused them. Diarrhœa set in the next day, with still greater depression and nausea. On the 30th, she seemed quite exhausted, and scarcely able to bring off the expectorations. We now began beef-peptonoids—a teaspoonful in hot water every two hours. It was retained on the stomach, and patient rather liked it. Milk and lime-water was given alternately with the peptonoids, and retained also. Aromatic confection and bismuth for the diarrhœa, and ether and respiratory stimulants, were also administered. On April 2nd, the diarrhœa abated; there was a shade less depression; the dyspnœa was, however, great. Respiration, 32; pulse, 100. On the 4th, the amendment was evidently maintained; respiration, 30; pulse, 100. By the 6th, the pulse fell to 84, respiration, 28; but the respiratory distress seemed unabated. Still the patient was able to bring up the expectoration more freely; and from this time the clogged tubes began to clear. With this there was a distinct revival from the oppressed condition, and various kinds of food were taken. Convalescence was, however, delayed until June; but, considering the patient's age and the severity of the attack, it is rather a matter of surprise that she survived it. All through April and part of May the "peptonoids" powder was continued, but, of course, less frequently, as other aliments could be taken. Up to the last, however, the patient would take it in the night, and pronounced it "very supporting."

WIESEN AS A HEALTH RESORT IN EARLY PHTHISIS, WITH DIRECTIONS FOR CLOTHING, DIET, AND EXERCISE IN THE SWISS ALPS DURING WINTER.

By A. T. TUCKER WISE, M.D.,

Formerly Visiting Physician to the Infirmary for Consumption, Margaret Street, Cavendish Square.

(*Continued from page 131.*)

Chapter II.

Site and Elevation of Wiesen. Its Neighbourhood. (5,050 *ft. above sea-level by the Calculations of the Swiss Meteorological Society;* 4,990 *ft. by Dr. Frankland;* and 4,771 *ft. from Dufour's trigonometrical measurements.*)

This small village stands about twenty-four miles from Chûr (Coire), on the picturesque Landwasser route.

About 11 miles further on, after presenting several structural difficulties and passing through the Züge gorge, the road winds into Davos.

The position of Wiesen exhibits many peculiarities and advantages as an Alpine health resort in winter. Situated on the slope of the Wiesener Alp, facing south and protected on the N. and E. by mountain ranges of 8,000 ft. and 10,000 ft. (Sandhubel, Foppa, Alteingrat, Leidbachhorn), it is effectually screened from the cold winds of winter. Sheltered equally on the southern and western aspect by the Buhlenhorn and huge Stulsergrat (8,390 ft.), the Tinzenhorn (10,278 ft.), and Piz St. Michel (10,374 ft.), and continuing the circle, by the Motta Palusa, Piz Toisa and Piz Curver (9,760 ft.), a land-locked region is formed, radiant in winter with dazzling sunbeams. A thousand feet below is the Landwasser chafing through a narrow course to join the Albula, a mile or so beyond.

Covering the slopes are innumerable pine trees. The odour from these is frequently perceived by new comers, and the antiseptic vapours exhaled presumably contribute to cure.

The most noteworthy feature of the vicinity is an extensive plateau partially filling up the N.W. side of the basin, and jutting out towards the centre, forming an excellent and picturesque promenade. The view from the border of this plateau is seldom excelled on a small scale. Far down at one's feet is seen the floor of the gorge, with the rushing of the Landwasser audible. A peep at the Albula Valley is gained, and beyond rises the Curvèr.

On the left lies the little village of Jenisberg; the Stulsergrat towering above. Behind to the east is the Alteingrat, Leidbachhorn, &c., and on the right the two hotels separated from the plateau by a small vale down which the road descends to the Züge, passing the Känzeli Waterfall.

A variety of attractive walks can be had in the neighbourhood. Limiting enumeration to a few within a short distance, the descent to the Jenisberg Brücke far exceeds all others in beauty. After repeated windings through a larch-wood a view is obtained of an undulating ravine densely overspread with dark green firs stretching away to the Albula Valley. The sound of the Landwasser becomes more distinct through the trees, and a few turns bring one abruptly on to the bridge.

The bridge itself is built of pine, and has the sides and roof of the same material. It spans the chasm without any central support, and some rough engineering skill is evident in its construction. The spectator avails himself of a small hole, cut on either side, permitting a sight of the yawning abyss beneath. To project the head and peer down at the Landwasser is most fascinating, and well worth the half-hour spent in making the journey. After leaving the bridge a few turns to the right will afford a fine front view of the Bärentritt. In this direction the return trip can be prolonged through the pines towards Ziegelhütte, returning to Wiesen by the Landwasser Road, occupying about one hour and a quarter.

Another walk which deserves special mention is to the Grosser Wasserfall. Passing through the village of Wiesen, distant about 200 yards from the hotels, and hidden from view by its position, the road makes several turns, and crossing one or two mountain torrents, reaches an open pasture. Traversing this and entering the forest, the waterfall is discovered in a secluded glade, affording a pretty glimpse at the peak of the Tinzenhorn.

The most frequented ramble, and one that has but a slight incline, is the Landwasser Road in Chûr direction, proceeding as far as the Tiefentobel. A commanding view is obtained of the Piz d'Aela (10,894 ft.) and the other lofty peaks on the south side of the valley. After passing over a stone bridge a tunnel cut through the rock is entered, and the road can be continued to Schmitten, about 2 miles.

By the same road in the opposite direction, towards Davos, the Känzeli Waterfall is an attraction. A small gallery jutting out from the roadway has been constructed here as a point of view from which the pedestrian can see the torrent on the right, losing itself amongst the pines of a wild and rugged ravine. A continuation of the walk takes one on to the wonderful Züge gorge.

The Wiesener Alp can be ascended by passing through the village and taking a turn to the left, a directing-post indicating the way. The ascent is easily made at any time except immediately after a heavy snowfall. The pathway is good, and leads into the pine-woods. From a little eminence a pleasant view is obtained of the valley and surrounding mountains.

Other excursions might be named which could be undertaken on foot or by sleigh. In the western division of the village are two hotels, each of which can accommodate from thirty to forty persons. Up to the present time mostly summer guests have frequented the place, but arrangements are now made to receive those whose health compels them to reside at a high altitude during the winter season. The proprietors furnish good *cuisines*, and the quality of food compares very favourably with that at Davos, whilst the cost of living is less.

Chapter III.

The Climate of Wiesen.

Material assistance in describing this will be rendered by a contrast with Davos Platz.

No one has at any time seriously made the attempt to uphold Davos as faultless; nevertheless, in the present instance it will serve a very convenient purpose to recognise in the well-known Alpine station a suitable standard for comparison.

To disarm criticism, as far as observed facts are concerned, nothing has been designedly omitted which would appear prejudicial to Wiesen. The drawbacks, as well as the advantages, are shown, to enable a correct judgment to be formed of the place and the class of cases it is likely to suit.

Distant 11 miles from Davos, 334 ft. lower in altitude, and with a different contour of land, slight modifications in the meteorological details may be anticipated; whilst the general character of a cold, bracing, and stimulating climate is maintained. The chief points of variation from Davos are—its position on the side of a hill; sparser population; slightly higher and more equable temperature, with less wind. Wiesen may be considered to be about 2 or 3 degrees warmer than Davos, and, although an increase of mean temperature might lead to the belief that dangers would arise from thaws recurring, the periods of liability to actual snow melting seldom take place with more frequency than in the latter valley. The intense heat of the sun sometimes renders parts of the main road damp under-foot when the snow is discoloured, but this could be greatly remedied by removing or covering all dirty patches as soon as formed. The plan of cleaning the roads in this manner is adopted at Davos, and would, no doubt, be undertaken at Wiesen if the number of visitors increased.

With a higher mean temperature, of course the winter is shorter compared with Davos: this might be two or three weeks at the commencement of cold weather, and about the same at the termination of the winter. During the worst time of snow-melting in Davos (which happens either in March or April, according to the mildness or severity of the season), Wiesen clears of snow rapidly; and there being no flat and marshy valley below, like at Davos when the snow melts, any injurious consequences proceeding from dampness and evaporation from marshy land are avoided. The hard frosts at night during this period depend much on terrestrial radiation and gravitation of cold air: the larger sky expanse presented to the Davos Valley favours the former, whilst the situation of the village is low. The bad part of the winter season is then much prolonged, as the warmth of mid-day and afternoon causes a thaw. The evening and night change the wet snow into ice, and so delay its speedy disappearance. An early clearance of snow makes Wiesen a desirable locality for a change from Davos towards the end of the season. Or by judiciously-timed transits from one place to the other much of the bad weather can be escaped at either station in the months of October and March. The journey can be made within two hours, and if a tolerably fine day be selected, little risk is incurred, even in an open sleigh. Covered sleighs may be chosen; but with plenty of wraps, in bright weather an open vehicle is much to be preferred. Neither would it be at all a perilous test if the experiment were made of sending cases here when Davos was found to be unsuitable for them. If satisfactory progress were not induced, the patient would be spared the long drive to Chûr or Lanquart. The deplorable results which have taken place after sending people who were seriously ill from Davos on to Thusis and Ragatz in cold weather perhaps supports this suggestion. On the other hand, the advisability of making a rapid descent from a high altitude to the low-lands, even for convalescents is questionable. Many patients, when leaving Davos for the plains, lose much of the ground they have gained, in consequence, it may be, of the fatigues of travelling, exposure to windy or damp weather, neglect of ordinary precautions or care in personal management. Dr. Spengler, of Davos Platz, makes a statement which not only suggests the need of investigation into this matter, but also raises doubts as to whether the "high altitude cure" can be considered a permanent cure or not; in other words, if the advantages gained by breathing this mountain air are lasting, and if persons can return to their old occupations with impunity:

"Un médecin, residant à Davos, a observé, durant une pratique de treize ans, non seulement que l'état sanitaire et les rapports de la mortalité sont des plus favorables parmi les habitants de cette vallée, mais encore que les cas de phthisie pulmonaire, en particulier, y sont complètement inconnus ou tout ou moins extrêmement isolés. Par contre, il a vu des natifs de Davos, tels que pâtissiers, cafetiers, etc., qui, après avoir échangé le séjour de leur vallée contre celui de grandes villes de l'Europe, sont revenus à Davos avec tous les symptômes de la phthisie pulmonaire. Mais lorsqu'ils eurent aspiré pendant quelque temps l'air natal, leur santé s'améliora et finit par se rétablir complètement. L'arrivée de plusieurs malades suivit de près la publicité de ces constatations, et si le succès qui a couronné leur séjour à Davos n'a pas été aussi rapide que pour les natifs mêmes de la vallée, il n'en a été ni moins heureux, ni moins complet."

It would appear from these observations that a prolonged existence in Davos does not carry with it immunity from phthisis, even in presumably healthy persons with little or no hereditary predisposition to the disease. How much more, then, must "cured" patients be liable to a return of pulmonary symptoms?—when are these likely to redevelope themselves?—when does the expanded chest shrink again? These are questions which will be answered, no doubt, by increased experience of Alpine climate.

Chapter IV.

Water Supply and Soil.

The water supply of the hotels appears to be of wholesome and excellent quality, it falls on the extensive surface of the Sandhubel, mostly as snow, and is filtered through the broad summit of the Wiesener Alp, where it makes its appearance in the wood by numerous springs. The springs selected to supply the houses are protected from cattle, &c., and the water brought down in pine-tree tubes to a tank on the hill, and from thence in iron pipes to the hotels; where in winter it is constantly running to prevent the pipes freezing. The likelihood of contamination is then at a minimum, as no storage takes place in the houses, nor are there any habitations above the level or in the vicinity of the mountain streams.

The water itself is without odour or flavour, and has a bright sparkling appearance from the carbonic acid taken up in the interstices of the rocky soil, through which the springs percolate. Although deprived of its oxygen in winter, by freezing when falling as snow, it becomes sufficiently aërated in its course from the springs to the tank.

It is probable that nearly all the springs at these altitudes in the neighbourhood of Davos closely resemble each other in their chemical constituents, therefore a reference to an analysis made by Mr. Philip Holland, of water found in the Davos valley will give some idea of the character of that at Wiesen.

"The general composition of the water shows the saline matter to consist chiefly of the carbonates of lime and magnesia with some sulphate of lime. They failed to yield either 'free' or 'albumenoid' ammonia when examined by the method of Messrs. Wanklyn and Chapman, nor were nitrates found. The chlorides, too, are in very small amount. They cannot therefore, presumably, have received sewage matter. The water used by the inhabitants is collected from small streams rising in the adjacent mountain sides, and is conducted to their doors from the higher to the lower level by iron pipes, and in some places, for the greater distance, by primitive wooden conduits common throughout Switzerland.

"The total solids yielded on evaporation varied from nine to eleven grains per imperial gallon. The following is an analysis of the water used for the table at the Hotel Belvedere. It flows from an iron pipe fixed in the wall on the mainroad, and close to the hotel:—

	Grains per Imperial Gallon
Carbonate of Lime	4·964
Carbonate of Magnesia	4·506
Sulphate of Lime	0·931
Silica with Oxide of Iron	0·232
Chlorine (calculated as chloride of sodium) ...	0·232
	10·815

Solids by evaporation, 11·10

The somewhat considerable proportion of magnesium carbonate will be derived from the Dolomite limestone, which is plentiful in places along the valley.

The other samples of water taken from other sources in the valley, have yielded results so nearly similar to the one mentioned that we have not deemed it necessary to insert the tables here, and the general inference to be drawn is that all the water in the valley is exceptionally pure." (*a*)

The condition and nature of the soil at these high level stations, presents an interesting subject of study, but one which it is impossible to deal with, at any length, in the limits of the present work. One or two of the salient features connected with the temperature, and quality of the land, must not however, be passed over.

The soil of these mountain pastures is thin, of a rich, fertile character, and absorbs roughly 1·4 (*b*) times its weight of water, underneath is the solid rock, mostly dolomite limestone, except in the centre and at the edges of the valleys or ravines, where lie the moraines of ancient glaciers composed of rubbish or deep earth intermixed with smooth blocks of rock and pebbles.

From the steep declivities on which moisture falls no injurious collection of water can take place. The drainage both of the surface and subsoil is rapid and effective. Being also of shallow depth, the danger arising from a heavy rainfall pressing up effluvia from the deeper strata, is obviated; and having also no stagnant underground sheet of water, the evolution af organic emanations, forwarded by constant moisture, is not aided; or if these decompositions do occur, it is probable that absorption of their deleterious properties, is mainly affected by contact with comparatively dry earth. Vegetation also, as short thick grass covering the slopes, speedily absorbs the

---

(*b*) 2 Kilos 500 grms. of soil taken from garden and dried, weighed 1 Kilo, 850 grms. on being wetted again and allowed to drain, weighed 2 Kilos, 600 grms.

products of decomposition. But the condition of the land with which we are principally concerned during the winter season, takes on altogether a changed aspect, and one which until recently has attracted little attention. Uninterruptedly covered with snow for about four months during the year, the ground itself assumes the nature of "sub-soil," whilst the layer of thick snow above the actual service, modifies in a marked degree the effects of telluric influence.

Occasional falls of snow assist to free the atmosphere also, from aërial germs and mechanical irritants, fixing them in a freezing medium; the former being destroyed or absorbed by the soil and vegetation, at the time of thaw; the latter being washed into, and mixed with the earth. Under these circumstances it is apparent that the air above is as pure as nature can possibly produce it—clean, dry, calm, and laden with balsamic vapours from the pines.

The system of drainage, for a scantily populated locality, is safe enough. Cesspools are placed on the sloping land at some distance from the hotels. The form of water-closets, however, is bad, as in most Swiss hotels. Promises are made that these defects will be remedied, and that for the forthcoming winter a skating rink will be constructed with other improvements, if the number of visitors admits of the outlay.

(*To be continued.*)

POSITION IN LABOUR. (a)

By A. DRUMMOND MACDONALD, M.B., C.M.Edin.,
Liverpool.

Mr. President and Gentlemen,—Position in labour is not a matter of routine, but of careful thought and attention, especially during the second stage, and it is to position at the conclusion of this stage that my remarks will be almost entirely restricted.

Defining the position to be assumed by the patient, Dr. Playfair, at page 330, vol. i., second edition of his work, says (and I am not aware that the words have more recently been altered): "In this country it is usual for her to lie on her left side, with her nates parallel to the edge of the bed, and her body lying across it. This is the established obstetric position in England, *and it would be useless to attempt to insist on any other, even if it were advisable.*" The italics are mine.

Gentlemen, however much I may be inclined to bow to those dicta of so eminent an obstetrical authority which are the fruit of ripe experience, I am bound to say that I cannot accept a dictum such as this, shutting out as it does position in labour from a share in the scientific progress of our age. And I am here to argue for—and, if possible, to persuade you to think advisable—a modification of the presently practised British position.

The position above defined is assuredly that in which obstetric operations are most conveniently commenced, but I hope to show that it is not the position in which to terminate either operations, or those cases, the vast majority of all labours, where the natural powers suffice. Previous to the descent of the head upon the perineum, we may determine the amount of permissible flexion of the thighs by observing the amount of apparent reflexion after straightening the limbs, which takes place at the onset of an uterine contraction. This is my guide to position curve during the greater portion of the second stage. But the position which I desire to find applied in terminating all, or nearly all, labours is that which I have termed the Straight-bodied, or (for the lovers of classic expression) the orthodematic position—a right or left-sided position, with the lower extremities adducted and placed as nearly as possible in the line of the body axis.

Dr. Hurt, of St. Louis, first applied the principle to American obstetrics, and in the beginning of December last I advocated its application to the British right or left lateral position, it being a matter of simple convenience whether the patient lies on the right or left side. I was glad to observe, in addition to some favourable private testimony, that a distinguished member of our Association—Dr. Edis—at a meeting of the Obstetrical Society of London, reported in the *Journal* of 6th January last, also confirmed the principle.

What then happens in the curved position? Briefly this: An artificial tension is induced by the dragging of the skin of the nates and posterior aspect of the thighs on the perineal tissues through the skin and subcutaneous tissues over the base of the perineal body and fourchette (abundant adipose tissue is, I think, a contributor—in primiparæ, at least); and also I believe some amount of resistance to distension of the pelvic outlet is produced by the tension or traction of the stretched *glutei maximi* on the coccyx and posterior surface of the great sacro-sciatic ligaments. In this acquired tension the powers of parturition, or the obstetrician's arm, or both, find an additional element to be overcome, which is also met by the presenting part a little nearer the perpendicular, so that increased power is demanded, and the force not only overcomes the resistance, but does so by more or less solution of the continuity of the resisting body—the vulvo-perineal tissues. Whereas in the straight attitude the natural obtuseness of the angle of inclination of the perineal plane is preserved, and whatever laxity of parts is present is not interfered with—thus by diminished resistance expediting labour and helping to maintain the integrity of the pelvic floor.

Now, in endeavouring to prove my averments, I must hold laceration or non-laceration of the perineum to be a practical test by results. Collateral and accessory influences, such as careful guidance and control of the head, delivery of an arm if possible before the shoulders, support while they are passing, suspension of the accessory powers, and so on, have, no doubt, equal sway in each of the two sets of cases I am about to compare, since the efforts of accoucheurs have long been directed towards all perineal-saving points—one excepted—and that one, *the position of the perineum itself.*

The figures relating to the curved position are high. Thus, Dr. Matthews Duncan quotes Shroeder as putting them at 61 per cent. for injury to the "perineum" itself, whilst Dr. Duncan's deputies at the Edinburgh Maternity experienced on the most favourable view 52 per cent. of perineal laceration in a series of twenty-five unaided primiparous cases, delivered presumably more or less in this curved position. He refers slight lacerations of the posterior commissure under half an-inch in linear extent to the fourchette, and this definition of "fourchette" I am willing to adopt for the purposes of comparison. Accordingly in that series we find thirteen instances of laceration of the perineal body, four of the fourchette, and eight in which none of the so-called "inevitable" (lacerations) took place. I may cite as further examples of what that position alone can accomplish two cases of primiparæ coming under my own observation, but where I was not present when the child was born. One had assumed the dorsal decubitus with knees well drawn up; the other was delivered at stool. They were cases of head presentation at full time. The first child was of average size, the second over average, and both perineums were ruptured to the external sphincter ani. Obviously the position might be described as being curved in both instances. This completes that side of the question.

What have I to tell of the straight-bodied lateral position? Firstly, I rely upon the general statement of nearly sixteen months' experience of its beneficial results; and, secondly, I adduce special evidence derived from twenty-five primiparous cases, in which this position was used, as well as mention corroborative cases. Time will not permit of much detail—but, briefly, eleven out of the twenty-five were head presentation forceps cases, and in four there was no laceration, or only the "inevitable;" in four the fourchette was more or less lacerated; and in three the perineal body was in various degrees trenched upon (from slightly to within a quarter of an inch of the arms in a case of rigidity). Fourteen were unaided deliveries, and in ten the fourchette was entire, in three it was lacerated, and in one the perineum was half torn by both shoulders shooting down together. They were full time occipito-anterior presentations save one, a complex premature twin case of cord, footling, and back presentation, where I evulsed the second fœtus. I am free to confess that a desire to avoid the pubic Charybdis only to strike against the perineal Scylla may have partially accounted for the three forceps lacerations, as traction was probaby not made exactly in the axis of the outlet—a fertile source. I believe of lacerations in instrumental cases, and an argument for early removal of the blades, although the conditions of delivery will always produce some contrast between forceps and natural deliveries.

(a) Read at the meeting of the British Medical Association, Liverpool, 1883.

Regarding the children, I may state that one was weighed for me at 9½lbs., while there was the case of small twins already referred to. I weighed eight of the children myself, and the average of five females and three males was 7lbs. 8½ozs., one of these only causing slight rupture. The occipito-frontal diameter, measured shortly after birth, was 4⅞ inches fully in nine instances, and in four the average sub-occipito-frontal circumference was slightly over 12¾ inches. We thus see that the passengers were fully up to the average size, and that the conditions of labour in all the cases were such as to supply a test. Including, then, aided and unaided cases we find a record of only 16 per cent. of laceration of the perineal body, which, even in view of the very favourable figure through care being taken of Olshausen quoted by West (21 per cent. in primiparæ), goes to prove a considerable balance of practical influence to be accorded to an attitude whose benefit we theoretically at first glance perceive. Corroboratively, and as leading up to an universal affirmative proposition, I may mention in multiparæ an occipito-posterior, face becoming occipito-posterior, an occipito-posterior forceps case, a breech, and a case of podalic version, all delivered in the straight-bodied position without laceration.

As to the *method:* In unaided cases it is simply to place the patient longitudinally in bed to commence with (unless an extraordinary vaginal examination be requisite), and then to straighten the limbs as the presenting part descends upon the perineum. In forceps deliveries the patient's shoulders are brought round by the nurse parallel to the edge of the bed, while the operator holds tight his grasp; a little additional assistance places the patient further from the edge, but within convenient reach, a procedure in which there may be theoretical, but no *practical* difficulty.

In conclusion, you will understand the meaning which I wish fully to convey when I say that upon the integrity of the pelvic floor a great measure of the health and happiness of woman depends. What we have to think of is not how to repair, but how to prevent, laceration, both of its pubic and perineal, but chiefly of its perineal, segment. I have shown that a more or less sigmoid position tends to produce these lacerations, whereas a rectilinear position tends to prevent them. Is it not, therefore, advisable that we should abandon the "established" in favour of the straight-bodied position, as being more in accordance with the upright arrangements of Nature?

◆

A telegram has been received at the India Office from the Viceroy, dated Simla, August 14th, calling attention to the rapid increase of deaths from cholera at Bombay. During the fortnight ending July 7th the mortality was 32, and in the next fortnight 106, whereas for the last fortnight the deaths from cholera numbered 202.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Reported by JOHN W. MARTIN, M.D.,

Sheffield.

Gastro-enteric Symptoms, closely resembling those of Typhoid—No Rash—Tumour in the Right Iliac Fossa, over the Ileo-cæcal Valve—Persistently Furred Tongue—Great and long-continued Loss of Strength—Relapse after Partial Recovery—Constipation for some days: when Relieved, Stools Slaty-blue Colour, unstained by Bile—Reappearance of the Tumour in Iliac Fossa—Treatment—Recovery—History of Defective Sewage.

Was called in to see Mr. B. C., æt. 34, of Sheffield, on Saturday, the 31st of March, 1883. Found him rather feverish, and complaining of having been out of sorts for the preceding ten or twelve days with what he thought was indigestion, as he had loss of appetite, discomfort after meals, and irregularity of the bowels. When seen, the temperature was 101·4. This might be looked upon as the temperature of the fourth day of illness, as he was compelled to give up work on the preceding Wednesday, March 28. The tongue was heavily furred, with a triangular red patch at the tip, and prominent papillæ. The bowels had been moved on Thursday, the motion being thin, light coloured, and very offensive. They had not been moved since. Pulse 100, temperature 96. There was decided garguillment in the right iliac fossa and some tenderness, especially to deep pressure. The abdomen was tympanitic and slightly distended. The patient was very thirsty. He passed a fair quantity of clear, straw-coloured urine. He was restless, and had not slept comfortably for several nights. When asleep he dreamt heavily, and awoke tired and unrefreshed. On Wednesday, March 28, when first seized, he felt intense langour and pain in the small of the back and in the bowels. On inquiry, I found that for some time his wife and children were out of sorts, languid, and troubled with thirst, anorexia, irregular action of the bowels, and general malaise. Their tongues were dirty-looking, furred, red at tips, and presenting prominent papillæ. They had never, however, to be confined to bed. Further inquiries elicited the fact that there had been for some time something wrong with the house drain, accompanied by leakage, and fouling of the air of the cellar and of the passage leading to the entrance-door and back yard. This pipe was carried from the back of the premises, through the covered passage that gave entrance to the two neighbouring houses. Half-way through the passage, and opposite the entrance-doors of both houses, the pipe was broken, and allowed free escape of the drain contents. The effect was perceived in the passage, and strongly so in the cellar. For treatment, I placed him on effervescent citrate of potash mixture, with tr. of aconite and sweet spirits of nitre, and gave a composing draught of chloral hydrate, bromide of potassium, and morphia. I also applied turpentine stupes and hot linseed poultices over the abdomen, and directed his diet to be exclusively confined to slops.

April 1st (Sunday).—Condition much the same as on the previous day. Pulse, 102; resp., 24; temp., 101·4. No motion from the bowels since Thursday. Abdominal symptoms unchanged. Treatment continued.

2nd.—No motion from the bowels. Abdomen rather distended; tympanitis more marked; and the pain and tenderness in the right illiac fossa decidedly increased. Tongue presented a heavily furred and foul appearance. Passed a restless night. Ordered half-an-ounce of castor oil, to be given in some warm milk; other treatment to be continued.

3rd (supposed seventh day of illness! ?).—Pulse 92, dicrotous; resp., 24; temp., 100·6. No motion of the bowels on the 3rd, but they had been well moved after the oil the preceding day. First noticed a hard lump, about the size of a turkey's egg, but a little longer, in the right iliac fossa, just over the ileo-cæcal valve, extending downwards towards the inguinal canal, and lying parallel to the crest of the ileum. This tumour was dense, and resistant to the touch, and was not in itself painful. There was no fluctuation felt. Condition of the tongue unchanged. Felt very low and weak, and had not the smallest desire for food. I directed turpentine stupes and hot linseed poultices to be applied over the tumour, and continued the other treatment. In the evening the pulse was down to 88 beats in the minute; respiration, 24, as in the morning;

and the temperature, 101·6. Complained of great thirst. Dozed a good deal during the day. The face pale, with the exception of a flush over the cheek bones. Pupils of the eyes dilated. Other symptoms unchanged.

4th (eighth day of illness).—Pulse, 80, stronger and steadier; resp., 16; temp., 99. Not so thirsty. Bowels unmoved since the 2nd. The abdominal tenderness diminished. Slept well. No change in the size of the swelling observed. Gargouillement difficult to get. Ordered another dose of castor oil. In the evening the pulse was 72; resp., 20; temp., 99·6. Had three motions since morning—thin, and light yellow in colour, and very offensive. Felt restless and somewhat excitable. Passing water freely.

5th (ninth day).—The pulse, 72; resp., 20; temp., 98. No motion. Passed a restless night. Tongue unchanged. Treatment continued. *Evening visit.*—Tongue less furred. Dozed a little during the day. Pulse and respiration same as in the morning; temp, 99·8. There was less pain and tenderness over the ileo-cæcal valve. Tumour was slightly diminished in bulk. The pain in the back was much better.

6th.—Slept well. Pulse, 76. resp., 20; temp., 98·4. Bowels moved once since last evening's visit. Slight headache. Tongue cleaner. Appetite returning; feels a desire for food. Thirst less. No change in the tenderness felt over the right iliac fossa. I ordered the turpentine stupes to be continued. *Evening visit.*—The edges of the tongue moist and clean. Passed a good night. No motions from the bowels. Passing water well. The condition of the lump in the right iliac fossa remains unchanged; tenderness not quite so marked. Pulse, 64; resp., 26; temp., 99.

8th.—Condition of the tongue continues to improve from the edges towards the centre. Slept well. Free from headache. Pulse, 72; resp., 20; temp., 99·2. No change in the tumour. No motion from the bowels. Ordered treatment to be continued, and half an ounce of castor oil to be given.

9th.—Tongue improved, cleaning, and the papillæ not so red or prominent. Slept well. Had two motions after the oil. Pulse, 60; resp., 14; temp., 98. A very slight diminution in the size of the tumour.

10th.—Tumour decidedly smaller. Slept well. Appetite improving. Pulse, 68; resp., 16; temp., 98·6. No motion.

11th.—No motion. Very little tenderness in the right iliac fossa. Pulse, 80; resp., 16; temp. 99.

12th.—Complains a good deal of flatulence. Had two dark bilious looking motions. Tumour larger than it has been the last two days, and return of tenderness. Complains of a sharp pain about the umbilicus. Tongue the same as before. Pulse, 84; resp., 20; temp. 100. Ordered turpentine stupes and poultices. Patient begged me not to put a blister on. I also ordered the following mixture:—

℞ Sodæ bicarb., ʒj.;
Bismuthi trisnit, ℈ij.;
Tr. nucis vom., ʒss.;
Sp. amm. aromat., ℥ss.;
Tr. zingeberis, ʒj.;
Syrupi, ℥j.;
Aquæ chloroformi, ad ℥xiii;

M. ℥j. every 4 hours.

April 13th.—Flatulence relieved: tumour less tender, diminished in size; no motion. Pulse, 76; resp., 16; temp. 99.

14th.—No change in general condition. One motion, dark, and loose. Pulse, 64; resp., 16; temp., 99·2.

Changed the mixture for

℞ Acid. nit. mur. dil., ʒij.;
Tr. nucis vom., ♏ix.;
Succi taraxaci, ʒvj.;
Syrupi zingiberis, ℥j.;
Aquæ chloroformi, ad ℥viij.

M; ℥j. four times a day.

15th.—Tumour smaller, and less tender. No motion. Pulse, 72; resp., 20; temp., 99. Tongue cleaning towards the centre.

16th.—Tumour scarcely to be felt. Tongue almost clean, but still presents a central patch, which is coated with fur. No motion from the bowels; ordered an enema to be given instead of medicine. Pulse, 72; resp., 16; temp., 98.

18th.—The enema acted freely and comfortably. Pulse, 68; resp., 16; temp., 98.

20th.—Tumour seems to have disappeared. No pain or tenderness in the right iliac fossa. Sleeping well; appetite good; better than the supply of food. Tongue somewhat more furred and dirty, without any apparent cause for it. Pulse, 68; resp., 16; temp., 98. The general condition of affairs was so much improved that regular attendance and notes of the case were discontinued.

I was again asked to see Mr. C.

May 8th.—Had not been feeling so well for the past few days. On the preceding day had felt a violent desire to empty the rectum, but though he made many efforts to do so, he could get nothing to pass. He tried several enemas, but they failed to influence the obstructing mass; finally, he had to remove it by direct means. After overcoming the obstruction, he passed a large, slaty-blue, clayish motion, very offensive, and apparently wanting in the bile elements. I have never seen quite such a coloured stool before. Tongue furred, and bilious coating; the first being bright yellow as if covered with bile. Pulse, 120, weak, and compressible; temp., 101·3. The surface of the abdomen was very tender, especially in the old weak spot—the right iliac fossa. No lump to be felt there after the most careful examination. The ascending and transverse colon very tympanitic (drummy). Complained of severe headache. Urine sufficient, normal in apperance. I directed a light nutritious diet, and ordered

℞ Sodæ sulph., ℥ss.;
Lucci taraxaci, ℥j.;
Sp. eth. nit., ʒij.;
Tr. aconiti, ʒj.;
Gycerine, ℥j.;
Aquæ chloroformi, ad, ℥viij.

M. ℥j. four times a day.

Not having had any sleep the preceding night I ordered a sleeping draught as follows:—

℞ Potass. bromidi, ℈ij.;
Chloral hyd., ℈ijss.;
Syrupi, ℥j.;
Aquæ ad ℥iv.

M.. Half to be taken at bed time; the rest in two hours, if necessary.

May 9th.—Tongue furred heavily. Pulse, 88; temp., 99·2. Had one motion since morning, of the same curious character as before, slaty-blue in colour. Had slept well, and had only to take half the draught. Felt thirsty. Less tenderness in the abdomen; the lower half very tympanitic. Passing a sufficiency of water, but darker in colour. Treatment continued.

10th.—The tongue continues heavily furred. Pulse, 88; temp., 100·2. Had two good motions, semi-solid, bile-stained, and more natural looking. Ordered a dozen calomel powders, 1-12th of a grain each; one to be taken every two hours until finished. Mixture continued.

12th.—Slight improvement in the condition of the tongue. It shows a tendency to clean in patches. Pulse, 72; temp., 98·4. Appetite returning. Had four motions since my last visit, still light coloured, and very offensive. The urine not so dark. A small lump again to be felt over the ileo-cæcal valve. No pain or tenderness complained of when handling it. Treatment continued.

15th.—Tongue decidedly improved. General symptoms improved. Pulse, 68; temp., 98·4. Motions regular; fairly natural. Feels very weak. Continued treatment.

18th.—Improvement slow, but steady. Recommended a change to the seaside. No change in the size or character of the lump.

21st.—Went to Bridlington. Was feeling better. Tongue cleaner. Bowels regular. Slight diminution in the size of the lump. To take whilst away—

℞ Potass. bicarb., ʒj.;
Tr. nucis vom., ♏xl.;
Sp. am. aromat., ʒiij.;
Infusi gent. co., ℥iv.;
Aqua, ad ℥viij.

M. ℥j. three times a day between meals. Also to take warm salt-water baths.

June 3rd.—Mr. C. called to see me upon his return from the seaside. Feels much stronger and better. Tongue remains slightly furred. Bowels regular. Motions of a proper colour and consistence. Has to be careful with his diet. Appears to be convalescing satisfactorily. The lump in the iliac fossa could no longer be felt. Was able to resume his duties as a book-keeper.

This case appears to me interesting from several points of view, and serves to illustrate the difficulty which I think everyone will allow to exist in clinical work, of securing those unmixed typical symptoms which enable us to classify our cases under some one or other of the various clearly-defined diseases rejoicing in a special nomenclature.

In the first place, I am convinced that there can be but little doubt that defective drainage was one of the chief factors in producing the train of symptoms from which Mr. C. suffered. This idea is well supported by the coincident derangement of the digestive system in the cases of Mrs. C. and of the two children. The question presents itself, Was the case one of typhoid fever of a mild type, and seen only towards its close? The facial expression, flushed cheeks, and bright eyes, with dilated pupils; the condition of the tongue; the presence of tenderness in right iliac fossa, and of garguillment; the dicrotous pulse, and the character of the stools, were all strongly suggestive of a case of this nature, but still were not sufficiently characteristic to allow of certainty. Additional evidence, I think, is to be found in the great prostration felt by the patient, which seemed to me to be disproportionate to the severity of the attack, and also in the slow tedious convalescence.

As to the nature of the tumour, I do not think that there can be much doubt as to its being due to plugging of the cæcum. There were no *acute symptoms*, which are usually associated with active inflammation of that portion of the bowel. The tumour was only detected on the 3rd of April, the supposed seventh day of illness, although the region of the right iliac fossa had been subjected to repeated examination before that date. There were no symptoms of perityphlitis. This tumour was certainly the cause of no little anxiety to me during the progress of the case, and its disappearance was a source of considerable satisfaction.

Against the idea of the case being typhoid may be advanced the absence of rash and the remarkable tendency to constipation rather than to diarrhœa that existed.

◆

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Halifax, Wolverhampton 11; Birkenhead, 12; Blackburn 13; Bradford, Derby, Portsmouth, Huddersfield, Oldham, Edinburgh, 14; Bristol, Norwich, Bolton 16; London, Cardiff, Leeds 17; Nottingham, Birmingham, Hull, Brighton 18; Leicester, 19; Dublin, 20; Sunderland, Plymouth 21; Newcastle-on-Tyne, Preston 22; Sheffield, Salford, Manchester 23; Glasgow 24; Liverpool 26.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 22, Bombay 25, Madras 35, Paris 22, Geneva 18, Brussels 28, Amsterdam 20, Rotterdam 15, The Hague 24, Copenhagen 23, Stockholm 25, Christiania 19, St. Petersburg 28, Berlin 52, Hamburg (State) 24, Dresden 29, Breslau 34, Munich 37, Vienna 26, Prague 31, Buda-Pesth 31, Trieste 30, Rome 27, Turin 29, Venice 22, New York 41, Brooklyn 39, Philadelphia 27, Baltimore 28.

The principal zymotic diseases caused no death last week either in Norwich or in Wolverhampton. The death-rates from measles were 1·4 in Salford and 1·7 in Liverpool; from scarlet fever, 1·6 in Leeds, and 1·9 in Sheffield; from whooping-cough, 1·1 in Salford and 1·2 in Derby; and from diarrhœa, 3·0 in Salford, 3·5 in Plymouth, and 6·4 in Preston. The death-rate from diarrhœa, which was equal to 1·2 in London, averaged 1·8 in the twenty-seven provincial towns. The 31 deaths from diphtheria in the large towns included 21 in London, 2 in Glasgow, and 2 in Manchester. Small-pox caused 2 deaths in London, 2 in Birmingham, 2 in Leeds, and 2 in Newcastle-upon-Tyne.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 22, 1883.

AN INCIDENT IN ANTI-VACCINATIONIST TACTICS.

The progress of anti-vaccination tendencies is not making pace to the satisfaction of the band of agitators who have assumed the responsibility of instigating opposition to the law. They are consequently continually on the *qui vive* to seize any opportunity that may present of advertising the cause to which their energies are devoted, and of compelling the adhesion of the ignorant to anti-scientific principles. We have had occasion to refer to a good many of the manœuvres of the party in the past, but in no instance that has come under our notice has the thoroughly unreasonable nature of the anti-vaccinationists been so clearly demonstrated as in proceedings which characterised a meeting held on Wednesday last at Deptford. This gathering was, according to the chairman's opening statement, "called under pressing and peculiar circumstances. He held in his hand a certificate, duly signed by Dr. F. Fisher, of Deptford, to the effect that he had during last week examined five children in the locality, whom he found to be suffering from syphilitic eruption, which appeared shortly after vaccination by the public officer." The report from whence this interesting statement of professional candour is extracted goes on to say that "the certificate was read amid groans and hisses;" but that these marks of public opinion were not directed against the medical certificate itself is sufficiently shown by the fact that the meeting was induced by the eloquent utterances of a lady orator to unanimously attest how "This meeting of inhabitants of Deptford, having had laid before them a statement that there are good grounds for believing that disease has been communicated to five children in this district by vaccination, urgently requests the Local Government Board to grant an official inquiry."

As a mere ebullition of popular feeling, excited by an appeal to the ignorance in which the public is steeped on this question of communicated disease, the whole occurrence would be too contemptible to deserve notice. It does, however, derive importance from the association of Mr. Fisher's name with the affair, inasmuch as this gentleman has virtually endorsed a nonsensical conclusion, in the name of the profession of medicine. It may be, of course, that he was unaware of the use that would be made of his "certificate;" but, in any case, his knowledge of disease and its inheritance should have been sufficient to guard him against committing so grave an error as that for which his name is urged in authority. Every practitioner of experience among the lower classes of town populations, and especially of such localities as Deptford and the East-end of London generally, is, or should be, familiar with the fact that it is safer to expect a syphilitic taint in certain children than to ignore its possibility; and also it ought scarcely to be necessary to infer that medical men in actual practice are acquainted with the variations in respect to time observed in the development of the signs of syphilis among children.

The number of infants, offspring of parents from the lower ranks of life, born with inherited tendency to specific disease, is in all probability vastly greater than is even yet appreciated, or can be understood by those who are unfamiliar with the wide diffusion of such taint among less cleanly and careful inhabitants of cities. The children that result from marriage of such more or less diseased individuals must naturally be physically unable to resist many forces that would react harmlessly on more inherently healthy infants; and any interference with their constitutional state, vaccination for instance, will immediately develope the special tendency transmitted from the parents. In this way is it that the act of vaccination is so frequently credited with occupying the position of *auctor mali*, whereas it is in reality nothing more than the fan which excites a smouldering fire to blaze forth. The acceptance of this truth is it must be admitted, consequent on modern demonstrations of the meaning of disease, and could not be entertained with the theory which describes all kinds and degrees of illness as a material and specialised entity. But even the most conservative practitioner, adhering obstinately to the dogmas that found acceptance in the ancient time when supposition and fact were held to be synonymous terms, must be credited with common sense enough to enable him to grasp the reality of demonstrations which do not admit of dispute; or, failing this, such a one must feel no surprise if his defence of exploded ideas compels him to occupy a minority position in his professional relations.

Mr. Fisher is in this unfortunate position just now. If his "certificate" is a *bonâ-fide* testimonial of belief, then he is curiously out of accord with modern scientific discovery. Against the assertion he advances must be arrayed the probability of pre-existing tendency to disease which becomes apparent on the application of the stimulus afforded by vaccination. Unless he can uncontestably prove this is not a tenable proposition he cannot ask to have his own belief, however strong, accepted against the the teaching of long experience and of scientific investigation.

From a purely humanitarian point of view, the frequency with which syphilitic eruptions follow vaccination is a subject for congratulation. In the vast majority of cases the disease is inherited, and excited to evidence itself by the irritating influence of vaccination; and in this way early treatment is resorted to with prospects of success which could never be entertained if the infection lurked unrecognised for years in the system of the child. This aspect of the subject is never dwelt on by the fanatical band of opponents to the Vaccination Acts. They know too well how much truth it veils, and that the possession of it by the masses to whom they address their wild appeals would assuredly result in their own immediate downfall. But, while the low motive of personal interest may be held to excuse their actions, nothing can lessen the grave responsibilities of a member of the medical profession, however obscure and insignificant, who so far forgets the dignity of his calling, and the allegiance he owes to its traditions, as to pander to a demagogic hatred of that law which compels the preservation of health and a rigid observance of hygiene.

PETTENKOFER'S THEORY OF CHOLERA INFECTION.

Amongst the most recent contributions to medical literature in Germany is Dr. Pettenkofer's article in the *Neusten Nachrichten*, on the situation of Munich with respect to cholera. He asserts that in its epidemic diffusion, cholera is not only dependent upon an infection capable of being spread (or a cholera-germ) but is further aggravated or modified by the susceptibility of various localities. Some cities have always enjoyed a practical immunity from cholera, as for instance, Stuttgart, Salzburg, Lyons, and Versailles. The susceptibility of places not enjoying this local immunity, however, is not always alike. Thus, Munich has since 1831 only had three outbreaks of cholera, while Berlin has been subjected to the visitation more than twice as often during the same period; thus, the predisposition of a city for cholera arises from a combination of circumstances of place and time. Dr. Pettenkofer quotes several instances from the medical history of India in proof of his theory, as to the localisation of cholera infection in certain *places*, in contra-distinction to its emanating from cholera patients.

The arguments deduced from the fact of cholera being met with in ships, which move from place to place, are met with the assertion that ships have a right to be included amongst the localities enjoying that practical immunity to which reference has been made. It is remarked that according to the usual custom, if a ship is in an infected harbour and cholera makes its appearance on board, all intercourse with the shore is interrupted, and the vessel removes to the open sea, where the cholera usually becomes extinct. Statistics of an interesting character are quoted, with a view of showing that the cholera at sea (though attracting, when it occurs, an important share of public attention) really bear an extremely small proportion to the vast number of cases in which no such attacks take place. During the year 1873 there arrived at New York 152,135 persons from the continent of Europe, and the total number of deaths from cholera, on the way or during quarantine, is said to have been 8, of which 4 occurred on board one ship amongst the members of two families, who seem to have been already infected when going on board. The whole of the 11 persons were attacked, but the remaining 7 recovered after reaching land.

It is admitted that vessels have sometimes been obliged to turn back on account of the disease having attacked relatively large numbers on board, but it is pointed out that in such cases the common local origin of the disease has been clearly demonstrated; having been traced to certain lodging-houses with respect to emigrant ships, and to certain garrison towns where the outbreak has occurred on board war-transports. An instance is quoted of six companies of English soldiers having been sent by one steamer—three of them from a barrack, and three from a camp. Cholera broke out some days after the steamer was at sea, and numerous fatal cases occurred, but only amongst the men from the camp—those from the barrack as well as the crew, not having been attacked. A cholera germ may, it is asserted, be brought on board a ship; but in order to multiply and become infectious it requires to be brought on land again. Thus, when a certain time has elapsed, the germ usually dies; and it is to this circumstance that Dr. Pettenkofer attributes the fact that cholera has never been brought to England from India (notwithstanding the enormous shipping trade between the two countries) but has always reached England from the Continent of Europe.

With special reference to the history of the disease in Germany, account is taken of the fact that the epidemic development of cholera requires a certain time; the statistics referring to Saxony illustrating this principle by considerable mortality in any given year having been preceded by a much smaller number of deaths in the previous year. It is likewise asserted that the germ of cholera, when once sown in a place, does not in all cases manifest itself at once—the epidemic of 1854 at Munich having appeared during the autumn in certain portions of the city which had been free from it during the summer outbreak; the simultaneous nature of the original infection of the city being assumed.

The practical inferences which Dr. Pettenkofer deduces from the above facts differ to some extent from certain generally received opinions. While admitting that the keeping out of cholera germs or their disinfection and annihilation are radical measures of undoubted efficacy, he questions the possibility of these objects being carried out in their entirety. He disapproves of the systems of quarantine and of military cordons as being inefficient and as only resembling—even in their most perfect form—the means adopted by governments to prevent smuggling. The fact is, however, that smuggling does take place (though even on a small scale) in most countries. The evil to be guarded against is, however, very different in the instance of cholera infection, by reason of the rapid multiplication of the germs; and Dr. Pettenkofer argues that were dutiable articles endowed with this property of multiplication, fiscal suspension of the nature alluded to would never have been established, or would have been long since abandoned as useless. Details of the outbreak at Malta in 1865 are cited to illustrate these arguments.

It is further remarked that the present epidemic in Egypt is fully two weeks later than that of 1865, and the assertion is made that if the cholera localities in Egypt, and on the Mediteranean Sea have the necessary predisposition of season (as previously explained) the disease will again manifest itself in spite of all quarantine regulations; while if this predisposition does not exist, they will remain free from it, even if cholera patients arrive there. At the same time, reference is made to the fact that neither in Egypt nor in Malta has a winter epidemic ever been recorded.

THE SOUTHALL CATASTROPHE.

On Tuesday, August 14, Southall, near Ealing, was the scene of a most terrible fire, than which there are few calamities more calculated to impress the imagination with a feeling of horror. The building in which the fire occurred was a well-known private lunatic asylum licensed to Dr. Robert Boyd, and situated in a beautiful enclosure of some thirty acres, called Southall Park. The house was an old one, of historical interest, and was at the time of the accident occupied by Dr. Boyd and his family, and about twenty patients, with servants, attendants, &c. Fortunately a third of the full number of patients were away at the seaside and elsewhere, so that the possible fatalities were reduced to this extent. It is, however, with a feeling of extreme regret that we have to chronicle the fact that Dr. Boyd himself, one of his sons, two patients, and a domestic servant—five in all—fell victims to the flames. In the case of the chief sufferer, it is only too clear that he might have been saved had he been less solicitous to ensure the safety of all the patients under his care, for it was while essaying to reach those still in the house that he was overcome, his son being engaged with him at the time in the dangerous work of mercy.

Such a calamity must of necessity produce a very painful feeling of concern in many quarters. The only conditions under which asylum buildings can be constructed, if they are to serve the purpose to which they are applied, preclude the substitution of any passable barriers for the bolts and bars which are employed to secure doors and windows under existing arrangements. Locked doors and impeded exit are essential details in every institution of the kind; and so long as they are prominent features of a building, it can never follow that speedy evacuation by terrified inmates will be a feasible performance. But ingenuity is incompetent to suggest any improvement on the plan that finds adoption in every asylum, both at home and abroad, and hence reliance must be placed on precautionary measures alone for averting the recurrence of an accident like that reported from Southall. This will have the effect of exciting renewed inquiry as to the means provided for overcoming an outbreak of fire in asylums, should one by any means occur; and we may take it that no pains will be spared in any instance to make the appliances available in such emergencies as perfect as possible. In ordinary hospitals there are no less liabilities to fire than in asylums for the insane; and in the former the number of absolutely helpless patients is always in excess; but they nevertheless enjoy an immunity the latter cannot command, because of the absence of free communications between different parts of the buildings they occupy.

If any testimony were needed to show the entire devotion of asylum proprietors to the interest and safety of their charges, Dr. Boyd has rendered it in a fashion that has advanced him to the rank of truest heroism. Though seventy-five years of age, he steadfastly returned to the assistance of those he knew to remain behind in the burning house from which he had himself at first escaped in safety. By thus doing he sacrificed his life, and with him died also his eldest son. He had done a great amount of original work in the study of insanity, and was universally esteemed as an authority on the subject. His mode of death adds additional lustre to a name already associated with the achievement of good and useful work.

◆

Notes on Current Topics.

A Product of Sentimental Legislation.

In his twenty-sixth annual Report, the medical officer of health for the Holborn district, Dr. Septimus Gibbon, adverts to the mischievous effects that must necessarily flow from the success achieved by Mr. Stansfeld in his crusade against the prevention of disease. Dr. Gibbon has to announce an increase in the number of cases of venereal disease in the district under his own control. The numbers given are—syphilis 73, congenital syphilis 27, as against 52 and 24 respectively in 1882. Even this statement, however, he regards as very much underrating the frequency of the disease, and attributes the higher returns to increased courage of doctors in recording its true nature. The deaths from syphilis in the whole metropolis, which in 1881 were 551 in number, fell in 1882 to 517, or at the rate of 6·1 per cent. While commenting on the insignificance of this rate of decrease to the ordinary reader, Dr. Gibbon remarks that it is a fact of vast and far-reaching importance to the physician, who knows that syphilis is the prime cause or parent, as it were, of a legion of other diseases that are classified as still-births, premature births, snuffles, thrush, bronchitis, pneumonia, marasmus, water on the brain, consumption, paralysis, insanity, and diseases of the throat, skin, brain, and liver, as well as various forms of blindness and deafness. A practical opinion of this kind is well worth recording; and few will be found to disagree with Dr. Gibbon's verdict, that "it is a matter of the deepest regret that these Acts, which have done more for the public health than all other sanitary legislation put together, have been unconditionally repealed and abandoned by the Government, because, on a chance vote of considerably less than half the members of the House of Commons the following foolish and sentimental resolution was carried:—'That this House disapproves of the compulsory examination of women under the Contagious Diseases Acts.'"

The Jerrybuilder.

"A South Londoner" writes in incredulous amazement at the alleged discovery by the local authorities that they have the power to prevent the use of garden mould as mortar. He says:—"I have hitherto understood that London builders may use whatever they like, so long as they cover it up decently from public view. I am a tenant of a speculative builder who openly uses garden mould as mortar. The best part of the mould in my denuded garden I bought from my landlord from a heap which was being converted into mortar. District surveyors know perfectly well that not only garden mould, but even the contents of dust-carts, go to make up what in London openly does duty as mortar in the construction of human habitations, but which in a decently-governed little provincial town would scarcely be allowed in the building of a pigsty. The houses to which I refer are rented at £50 a year, and are not considered to be 'jerry' built. The garden mould is principally used as mortar for plastering the walls of the rooms inside. It is considered much too good for use as ordinary mortar, as it costs 3s. per yard. Ashes—that is, dust-cart refuse—and ballast are used as ordinary mortar." Nearer home we know a suburb in which a field was much lower than the public road beside it. For years its owner considerately informed the public that "rubbish may be thrown here," an invitation which was responded to by the deposit of thousands of tons of ash-pit refuse, numerous dead cats *et alia talea*. The ground having been thus raised to the required height, a row of Queen Anne's cottages have been built, the elegance of whose fronts is in the inverse ratio of the sanitary abomination of their foundation. Hereafter the inmates and their medical advisers will wonder at the advent of diphtheria, typhoid, &c., &c.

Tricycle Accidents.

There are few more remarkable developments of athletics than the rapidity with which bicycling sprung into favour and kept its position. It was, however, soon found that this admirable mode of progression was only suitable to the young, and that even to them there was a great liability to accident. There were, moreover, serious evils attendant on its continued use, not the least of which was the anxiety felt in any crowded place from the practical impossibility of standing still upon a bicycle. For females, of course, this mode of progression was out of the question.

The more recent introduction of the tricycle was welcomed on all hands, and it was used by middle-aged persons, and by ladies of all ranks, from Royalty downwards. It did not require the labour of learning to ride it experienced in its two-wheeled congener, and the rider could stop abruptly and rest at his or her ease as long as desired. Still it was objected that the legs were used at a disadvantage in progression, and that movement was accomplished by pure muscular strain, and not partly by muscle and partly by weight of body, as in the bicycle. All these arguments were met by the assertion, "Well, at all events, the tricycle is perfectly safe." Many recent occurrences would, however, show that it is nothing of the kind; and the most remarkable is the sad accident which occurred in London last week, and by which Captain Mayer sustained injuries which are likely to result fatally. Captain Mayer was proceeding along Aldersgate Street on his tricycle, and when near the Metropolitan Railway he attempted to go up Barbican. In turning round his machine, however, which he did too quickly, one of the wheels caught in the grating of a vent-hole, and the tricycle was overturned, Captain Mayer being violently thrown to the ground on his head. He was picked up in an insensible condition, and conveyed to a chemist's shop, where restoratives were administered and medical aid procured. In about a quarter of an hour he partially recovered consciousness, and seemed to be suffering intense pain, when it was also discovered that his left arm was fractured above the elbow. His arm was put up in splints, and he was removed to his residence in Piccadilly, where he now lies in a semi-unconscious condition, owing, the medical men say, to concussion of the brain.

The Health of Ireland.

THE quarterly return just published by authority of the registrar-general for Ireland, reports that during the quarter ended 30th June, there was registered in Ireland a birth-rate of 25·5 in every 1,000 of the population, representing an annual death-rate of 21·8. In England the birth-rate represented was 34·2, and the death-rate 20·0. The birth-rate in Ireland is slightly under the corresponding quarter of 1882, and also under the average of five years 1878-82. The deaths are above the corresponding quarter of 1882 by 3·8 per 1,000, and 1·8 over the average for the second quarter of the five years 1878-82. Compared with those for the corresponding quarter of 1882, pauperism shows a small decrease in the average number of inmates, and an increase of 3,726 in out-door relief. The deaths during the quarter amounted to 27,288 or 21·8 per 1,000, being 1·8 over the average for the corresponding quarter of the five years 1878-82. The death rate in Leinster was 24·6, in Munster 19·3, in Ulster 21·3, and in Connaught 18·1. In Leinster the total deaths are 787 above average. The deaths are above the average in all the counties except Louth and Westmeath. In Munster the deaths are 219 over average, there has been an increase in each of the counties except Waterford. In Ulster the deaths are 606 over average, there having been an increase in each of the counties. In Connaught the deaths are 613 over average, there has been an increase in each of the counties. The increase in the death-rate of the last five years is due to the excessive mortality amongst the old, the excess at all ages, being 1,260, and the increase in deaths at 60 years and upwards 1,289. Measles was prevalent, but, except in a few districts, not very fatal; the mortality from whooping-cough, exceptionally heavy in the preceding quarter, shows but a slight decrease, as, although the disease declined in many parts of the country, it was prevalent in portions of the province of Connaught. The annual rate per 1,000 of the population, represented by the deaths from the principal zymotics is 1·6 against 1·7 in the preceding quarter, and 1·4 in the second quarter of 1882. Ten deaths from small-pox were registered in Belfast, and 2 in Glennamaddy Union, but none in any other locality. Measles was prevalent throughout the greater part of the country, but, on the whole, the mortality was comparatively light, the total number of deaths recorded being 225, of which 60 occurred in the province of Leinster, 28 in Munster, 109 in Ulster, and 28 in Connaught. There were 337 deaths from scarlatina, viz: 39 in Leinster, 98 in Munster, 175 in Ulster, and 25 in Connaught. The total number of deaths from typhus last quarter shows no appreciable variation from that for the preceding three months or from the number for the second quarter of last year; it is 282, composed of 81 in Leinster, 102 in Munster, 57 in Ulster, and 42 in Connaught. In the first quarter of this year 501 deaths from whooping-cough were registered, and, owing to an increase of the disease in Connaught, the returns for the quarter now ended show but little diminution in the mortality, the deaths amounting to 491, viz.: 184 in Leinster, 27 in Munster, 140 in Ulster, and 140 in Connaught. The number for Connaught is 51 in excess of the number for that province in the preceding quarter, and this increase almost counterbalances the decline in the other provinces. The number of deaths ascribed to diphtheria is 58, which is considerably below average. Two hundred and five deaths from enteric fever were registered, being 21 under the number for the preceding quarter, and 15 under second quarter of last year. The Registrars in their notes report the prevalence of the following diseases:—Measles in 52 districts, scarlatina in 22, whooping-cough in 37, and fever in 23 (typhus in 9, typhoid or enteric in 9, and fever in 5). One death from hydrophobia was returned as having been registered during the quarter.

Diseases of Pre-Historic Men.

THIS subject has received some attention in a paper read by M. Le Baron before the Anthropological Society of Paris. Dr. Knapp, of New York, has also (*Archives of Otology*) studied the mound-builders from the standpoint of otology. As the result of an examination of two hundred and fifty skulls of the mound-builders, he found exostosis in forty-four cases. The condition was due to the habit of carrying foreign bodies in the meatus auditorius. Neither of these papers, however, compared in scope with that of Dr. Jackson, read before the West Kent Medico-Chirurgical Society. He (*Athenæum*) cited a case of exostosis in a femur found at Lozère; evidence of toothache and abscesses in the jaw found there and in the Belgian bone caves; of rheumatic ulceration of the joint in a jaw-bone and an astragalus from Furfooz, Belgium, and in other instances; a case of very extensive inflammation from the Caverne de l'Homme Mort, Lozère; a case of hydrocephaly from the Trou Rosette, Belgium, and one from the Canary Isles, observed by M. Verneau; hemiplegia in the skeleton found at Cissbury, Sussex; hip-joint disease in four cases recorded by M. Le Baron; synostosis of the sutures in the Neanderthal skull; and numerous cases of surgical and posthumous trepanation. He also expressed the opinion that syphilis is a pre-historic disease, citing examples of it from Bray-sur-Seine, in France, from Patagonia, and from Peru, and hazarded the suggestion that circumcision, which prevails in every division of the globe, and is almost universally performed with a stone implement, is a practice which has descended from pre-historic times. Flattening of the skull is known to have been practised, and fractures of bones and wounds of the skull are, of course, very frequent. Upon the whole it may be concluded that the diseases of neolithic pre-historic man did not differ much from those of the present day.

Duration of Cholera.

In a recently delivered lecture, M. Fauvel, Inspector-General of Sanitation in Paris, expressed his opinion that the more violently a cholera outbreak develops itself, the shorter is the duration of the epidemic. He also remarked that there was no danger of cholera being introduced into England by means of ships coming from India, and referred to the fact (also quoted by Dr. Pettenkofer) that the disease had always reached England in the past through the continent of Europe.

Muscular Contractions.

At a recent meeting of the Hamburg Society of Natural Science, Dr. Kotelmann read a paper upon the immediate causes of muscular contractions, which he classified as natural and artificial. To the former he referred impulses of the will and reflex motions. The latter only occur on the side of the body where the sensitive nerve is irritated, a transmission to the opposite side only rarely occurring, and then in a weak form. Artificial means of producing muscular contractions he divided into electrical, chemical, thermal, and mechanical methods. With respect to the first named kind, he remarked that constant currents produce effects different from those which are induced, while descending currents act differently from descending ones. Of chemical agents fixed alkalies, concentrated inorganic acids, and absolute alcohol are the most energetic. Alkaline salts and heavy metals are less powerful, and fatty oils are quite devoid of effect.

Physiological Research and Pigeon-Shooting.

By a majority of nearly two to one our hereditary legislators have given another year of impunity to the cruel slaughterers of the dove. Our legislation decrees that physiological research promoted for the protection of human life is a crime to be put down by law; and most effectually have they put it down, except in the case of a few favoured individuals, who work under licence, and under serious restrictions. When it becomes a matter of interfering with the "noble sportsman," however, it is quite another affair; and the peers, headed by Lord Redesdale, have declared, as far as in them lies, that the noble sportsman is to be let alone. The current number of a fashionable contemporary records that last week a member of our nobility won three pigeon-match cups; but no record is given of the number of pigeons massacred, nor could any record be made of the mutilation and dying agonies of the hapless creatures smashed with shot as they hovered dazed above the traps in which they had been confined. Probably there was more pain and suffering to the brute creation on that occasion than would occur in the physiological laboratories of the Empire in a year, and yet the law says to the investigator "Cease," and to the pigeon-match competitors "Go on."

The Cholera.

In addition to the various Commissions that have been despatched to Egypt for the purpose of studying the cholera, the German Imperial Health Office is also sending out one, at the head of which is R. Koch. If not already on its way, it will be in a few days.

A Heat Regulator.

Amongst the exhibits at the Sanitary Exhibition now being held in Berlin is an ingenious warmth regulator, exhibited by Herr Josef Leiter, of Vienna. By means of this contrivance, a water-bed, or douche, or bath, can always be kept at the same temperature, so that the necessity for disturbing the patient or intermitting treatment is avoided. It may not only be employed in regulating the heat of hot douches, &c., but also in the treatment of typhoid fever, when it is desired to reduce the temperature, in place of the ordinary and somewhat clumsy cold douches and baths. Such an apparatus will do much towards popularising the employment of cold in affections accompanied by dangerous pyrexia.

Epidemic Suicide.

Within the twenty-four hours of Thursday last no less than four young women resorted to suicide, two of them with fatal success. In three of the instances death by drowning was the mode selected for terminating existence, and the river Thames the medium chosen by each intending suicide. The fourth victim was a young woman, nineteen years old, who was so affected by the circulation of malicious stories reflecting on her character that she sought self-destruction by swallowing phosphorus paste. The other successful suicide was a barmaid, aged 21, who had been much depressed owing to being out of employment. She drowned herself. Each of the two remaining girls were rescued from death by the activity of bystanders, who took them from the water. One was nineteen, the other twenty-one years old; and unredeemed promises seem to have led to the act they were charged with. Such a batch of attempted suicides on the same day may be properly regarded as a fitting subject for reflection whether the verdict in fatal cases of "temporary insanity" is not something more than a kindly fraud. Although nothing in the manner or appearance of these four unfortunate young women would probably have led one to suspect that they were mentally astray, yet there can be but little doubt that they were actually *non compos mentis* at the time of making the rash attempt; and whether there was any connection between the period o the year and this demonstration of insanity may perhaps be speculated on with justice.

The late Professor Parrot.

There recently died in Paris, at the somewhat early age of 54, a physician whose solid contributions to practical medicine have rendered his name familiar to a large proportion of his professional brethren throughout the world. Parrot was born in 1829, at Excideuil, his father having been also a medical practitioner. He took the doctorate in 1857, and was appointed to the professorship of the history of medicine in 1876. In 1878 he was elected member of the Academy of Medicine, and principal physician to the Hospital of the Legion of Honour in 1879. The views which Parrot entertained as to rickets, which he regarded as a final stage of inherited syphilis, have served to render him a well-known authority in diseases of children; and the use of the terms "Parrot's bumps" and "natiform skull," for which we are indebted to him and his work, have assisted in perpetuating the name of a physician who laboured assiduously and successfully to assist the advancement of medical science, among whose leader she was least neither in importance nor in brilliance.

The Society of Naturalists and Physicians.

One of the most interesting gatherings of the year in Germany is that of the naturalists and physicians, last year held at Eisenach. The Society of Naturalists and Physicians, of somewhat older foundation than that of the British Medical Association, commences its fifty-sixth congress on the 18th of September, in the city of Freiburg in Breisgau. The city is not large, only possessing some 30,000 inhabitants, but it is not, however, lacking in interest. It boasts of a superb Gothic minster of the twelfth and thirteenth centuries with a magnificent tower 378 feet high (118 mètres), and a Catholic University founded in the fifteenth century. Visitors to Germany about the date mentioned will be well repaid by a visit to the congress. Tickets entitling the holder and lady to participation in all meetings, &c., cost 12s., and can be procured by application to the Secretary, Dr. Ad. Claus, Freiburg i. B.

Typhoid at Torpoint.

A very serious outbreak of typhoid fever has occurred at Torpoint in Cornwall, where, within a fortnight, nearly two hundred persons have been attacked by the disease. This has probably been introduced from some place in the district, the water supply of the town being most unfavourably reported on by the medical officer of health. A number of the cases have been traced to the influence of water obtained from a public well in the place; but the whole supply is so inferior that importation of the fluid for drinking purposes, in carts, is advocated. In respect to drainage, also, the town comes under official condemnation—no arrangements for flushing those drains recently constructed having been made, nor any precautions adopted for clearing the older pipes of the colonies of rats which infest them. Any continuance of such an undesirable state of things will, it may be assumed, be made no longer possible; and that immediate steps will be taken for remedying existing abuses may be taken for granted, as a consequence of the medical officer's report referred to. There is abundant need, in presence of the facts already stated, for searching and far-reaching hygienic reforms in and about Torpoint.

A Result of the Guiteau Trial.

The following instructive incident in connection with the trial of the late assassin, Guiteau, has been communicated to the *Boston Advertiser*:—P. J. Sheahy, who served as one of the jurors in the Guiteau trial, has become insane, and will be conveyed to an asylum. His insanity has been gradually developing ever since the hanging of Guiteau, which event seemed to have a powerful effect on a mind that before that time never showed the slightest symptom of weakness. Before the trial he frequently expressed the greatest repugnance to serving on a jury that was to try a man for his life, and after the trial he became morbid on the subject of being in part responsible for a hanging.

Dr. Wickham Legge delivered the second Bradshawe Lecture at the Royal College of Physicians on Saturday last, the subject of the lecture was "Cardiac Aneurysms."

◆

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

The Fever Epidemic at Kilbarchan.—The scarlatina fever epidemic which has prevailed in this village for more than six months now shows some signs of abatement. No fatal cases were reported during the week ending with Saturday, the 11th inst., nor were there any new ones, while in New Street, where the fever is most prevalent, almost all are showing signs of recovery. The public schools have not been re-opened yet. The sanitary authorities have been making inquiries and investigations with a view to improve the drainage and the present sanitary arrangements.

Health of Edinburgh and Leith.—For the week ending with Saturday, the 11th inst., the mortality in Edinburgh was 66, and the death-rate 15 per 1,000. There were 15 deaths under one year, and 11 above 60 years. Diseases of the chest accounted for 24 deaths, and zymotic causes for 6, of which 2 were due to scarlatina, and 3 to measles; the intimations for these diseases being 15 and 44. According to the public health return, 17 deaths had occurred in Leith during the same period, equivalent to an annual mortality of 14 per 1,000. Two of the deaths were cased by zymotic, and 13 by other diseases.

Public Baths in Edinburgh.—It is an extraordinary fact that in Edinburgh, where there is so much talk about public sanitation, there is not a single bath where the poor may indulge in the luxury of personal cleanliness. Edinburgh, we believe, boasts of possessing the oldest medical officer of health in the Kingdom, and yet, beyond the frantic efforts made with regard to the somewhat equivocal benefits derived from the notification of disease, there is really very little practical sanitation in the town. The water supply in many parts is deficient, the inhabitants of lofty flats having to go down to the street for their supply. The water-closet accommodation is of the worst description; the angles of the common stairs or the corners of the wynds and closes appear to be the chief resort of the poor people. Yet we hear of a death-rate of 15 per 1,000 amid all these surroundings. Surely with such a low mortality sanitary science may quietly be allowed to die a natural death. But we may be permitted to suggest an explanation for this low death-rate. During August nearly everybody who can afford to be out of town is absent, so that the death-rate is really that of the poor residents of the town. Certainly Edinburgh is a great sanitary success. It would be absurd, in the face of such favourable reports, to suggest that, if the money spent for the doubtful benefit derived from the notification of disease, as practised in Edinburgh, were spent in public baths and decent water-closets a better state of things would be the result.

Glasgow Death-Rate.—The death-rate in Glasgow for the week ending with Saturday, the 11th inst., was 25 per 1,000 per annum, as compared with 25 in the preceding week, and 21 in the corresponding week last year.

Forthcoming Sanitary Exhibition in Glasgow.—Professor G. M. Humphry, M.D., has been appointed to the presidentship of the Congress to be held in Glasgow at the end of September next. The inaugural address by the president will be delivered on Tuesday evening, 25th September, and the Congress will be brought to a close on the evening of Saturday, 29th, when a popular address will be delivered by Dr. Carpenter to the working men in St. Andrew's Hall.

Death of Dr. Arrott, of Dundee.—The death, at an advanced age, is announced of Dr. Arrott, long the leading physician in Dundee. Dr. Arrott graduated M.D. Edin. in 1829, and took the L.R.C.S. Edin. in 1872. He long occupied the position of physician to the Dundee Infirmary.

Dundee.—Royal Lunatic Asylum.—A special meeting of the directors of the Dundee Royal Lunatic Asylum, for the purpose of considering the present embarrassed state of the finances of the Board, was recently held in the Town Hall, Sir John Ogilvy, Bart., presiding. Ex-Provost Robertson, as convener of the new Building Committee, explained in detail the finances of the institution. It appeared that a debt of £50,000 was secured over the properties of the old Asylum and over the new Asylum, and that, in addition, there were floating debts unsecured of fully £10,000. The Provost explained the two modes which had been suggested for meeting the difficulty. The first was to promote a land company for the purpose of utilising the properties of the old Asylum, and thereby reducing the debt; whilst the second was to appeal to the generosity of the public to provide funds for paying off the floating debt, and thereby leave the Asylum with only its secured debt to work out in a gradual way ultimate relief. After a good deal of conversation and discussion, the meeting unanimously approved of an appeal being made to the public; but, as it was considered by some members that there might be a reversion on the properties, it was also suggested that the appeal should not simply be for donations, but for applications for debentures, to be secured by way of second bond over all the Asylum properties.

The Medical Bill.—A deputation of Scotch medical men had an interview with a number of members of Parliament on Friday last, to urge the amendment of the Medical Bill with respect to the representation of the Medical Corporations on the Boards which the measure proposes to establish.

"Tramps" and Fever in Glasgow—Dr. Russell, in his fortnightly report, says that the increase of enteric fever is always seen at this season of the year, but the increase of typhus is quite unusual. We have not for many years had 29 cases in one fortnight—not even in mid-winter. I have noticed for some time that cases in tramps were occasional, and probably the collection of all sorts of wanderers in the city during the Fair time may have something to do with this increase of typhus. At any rate, taken in conjunction with the fact that it has been epidemic in Liverpool for some months, and still prevails, the activity of this disease at this time is ominous for the winter. The Reception House has been unable to receive all the infected families into quarantine. It contains only 30 beds, and there are at present 35 inmates, and several families who are willing to go, and whom I wish to send, cannot be received. It is evident that the Reception House is too small for our requirements, and if another similar house could be obtained on the South-side it would be well. Reception houses must be near the various localities, otherwise adults object, very naturally, to live far from their work-places. It very seriously influences the efficiency of our operations against typhus not to be able to accommodate infected families while their clothing and homes are being cleaned and disinfected.

Vaccination in Glasgow.—At a meeting of the Health Committee a memorandum by the medical officer regarding defaulters under the Vaccination Act was read, and the committee agreed to recommend that the sum charged by the registrars for furnishing the information desired should be paid. He says:—The vaccination defaulters wholly belong to the class of the population who require special care and guidance in sanitary as in all their social relationships. I at present wish merely to satisfy you of the substantial advantages of this new branch of our work, so that it may be recognised and provided for permanently. The first lists of defaulters for the whole city referred to children born in the latter half of 1880. The last test of the results is to be had from the Registrar-General's annual reports on the Vaccination Act. The last published is for 1881. Previous to 1876 the proportion of the children born in Glasgow, who were not accounted for either by vaccination, death before vaccination, or postponement on medical certificate, was from 3 to 4 per cent. In 1876, and the three years following, when I confined our inquiries to the children born in the City Parish, this proportion was reduced to 2·81, 2·87, 2·97, and 2·88 per cent. In 1880, when for half the year the births in the whole city were operated upon, the proportion fell to 2·29 per cent., and in 1881, when the whole city was included, for the whole year, it fell to 2 per cent., *i.e.*, out of 19,076 born in that year 382 escaped the operation of the Act, instead of from 600 to 750 at the proportion which prevailed previous to our interference. If further proof were wanted that this improvement is the result of the special effort made in Glasgow, we have it in the fact that in the rest of Scotland, exclusive of Glasgow, the proportion of children not accounted for under the Vaccination Act has increased *pari passu* with our diminution. In 1877 it was 1·62, and has risen each year, until in 1881 it was 2·06 per cent. higher than in any one of the last ten years. Dr. Russell concludes by asking a small payment to the registrars for the increased labour entailed upon them.

The Registrar-General's Returns.—During the month of July there were registered in the eight principal towns of Scotland the births of 3,735 children, of whom 1,944 were males and 1,791 females. Of these, 3,431 were legitimate and 304 illegitimate, being in the proportion of one illegitimate in every 12·3 births; or the illegitimate births constituted 8·1 per cent. of the whole. 1,289 marriages were registered in the eight towns during the month. This number is 83 above the average for the month during the last ten years, allowing for increase of population. A comparison of the deaths registered in the eight towns shows that during July the mortality was at the annual rate of 13 deaths per thousand persons in Perth, 14 in Aberdeen, 17 in Edinburgh, 18 in Leith, 20 in Dundee, 22 in Paisley, 23 in Greenock, and 25 in Glasgow. Of the 2,179 deaths, 895, or 41 per cent., were those of children under five years of age. The miasmatic order of the zymotic (epidemic and contagious) class of diseases proved fatal to 386 persons, and constituted 17·7 per cent. of the mortality. This rate was exceeded in Glasgow, Greenock, and Paisley. Fever caused 27 deaths: of these 8 were tabulated as typhus, 18 as enteric, and 1 as simple continued. Six deaths from typhus were registered in Glasgow, 1 in Edinburgh, and 1 in Leith. Whooping-cough was the most fatal epidemic, having caused 97 deaths, or 4·5 per cent. of the whole. In Glasgow and Dundee 5·3, and in Greenock 6·4 per cent. of the deaths were ascribed to whooping-cough. Measles caused 92 deaths; diarrhœa, 82; scarlet fever, 34; croup, 19; diphtheria, 18; dysentery, 4; British cholera, 1; and metria, 1. In Glasgow, 5·7; and in Greenock, 6·4 per cent. of the deaths were attributed to measles. 43 deaths were ascribed to apoplexy, 59 to paralysis, 136 to diseases of the heart, 54 to hydrocephalus, and 63 to premature birth debility. The deaths from inflammatory affections of the respiratory organs (not including consumption, whooping-cough, or croup) amounted to 398, or 18·3 per cent. Those from consumption alone numbered 298, or 13·7 per cent. 88 deaths resulted from violent causes, of which 7 were suicidal. Nine deaths were attributed to the direct effects of intemperance, and two to delirium tremens. Three males and five females were aged 90 years and upwards, the oldest of whom was a retired farmer 98 years of age.

Medico-Parliamentary.

HOUSE OF COMMONS.—THURSDAY.

THE ANTI-VACCINATORS' MARES' NESTS.

IN the House of Commons on Thursday last, Mr. Hopwood asked the President of the Local Government Board whether his attention had been called to to the cases of five children now suffering severely at Deptford from syphilis communicated by vaccination from one other child; and whether a public inquiry into those and any other cases in the neighbourhood would be directed.

Mr. G. RUSSELL said the facts were not as stated in the question. There were four children, not five, and they were suffering from eczema. They lived in a state of squalor, which was favourable to the production of that disease. Under these circumstances, the Local Government Board did not think there was any ground for a public inquiry.

Mr. HOPWOOD asked the President of the Local Government Board whether he was aware of the deaths of two children in Shoreditch, as their parents alleged, from vaccination, viz., Charles James Kerridge, aged five months, vaccinated June 27th, became ill with eruptions over his body, and died July 13th; and Florence Edith Howden, vaccinated on 15th April, became ill in a few days with sores and abscesses, from which she never recovered, but died on July 13th; and whether he would direct a thorough inquiry into those cases.

Mr. G. RUSSELL said the Board had caused inquiry to be made into the cases of the two children referred to, and it was found that they both died from diarrhœa. The mother of the child Kerridge had no idea of attributing its death to vaccination, and the child had no eruption.

THE INDIA MEDICAL SERVICE.

Mr. GIBSON asked the Under Secretary of State for India whether the Secretary of State for India intended to direct an inquiry into the grievances of the India Medical Service with a view to meet some of the expectations with which candidates were induced to enter it, and to restore some contentment to its ranks.

Mr. CROSS, in reply, stated that it was not probable that any inquiry could add to the Secretary of State's information on the subject; and it was not proposed to make any change in the existing system by which officers succeed to substantive medical charges in India.

Mr. GIBSON said that, unless a remedy was applied in the meantime, he would at the earliest possible opportunity next Session call attention to the grievances of the India Medical Service and move a resolution.

THE CHOLERA.

ON Friday last, Lord E. FITZMAURICE informed Mr. D. Grant that Dr. Hunter had instructions to report on the whole subject of the cholera outbreak, and his reports would be presented to Parliament. One report had already been made, and it would be laid at once on the table.

THE EGYPTIAN MEDICAL SERVICE.

Mr. GIBSON gave notice that, owing to the lateness of the Session, he would postpone until next year his motion with respect to the evidence given by Lord Morley's Committee on the Medical Service in Egypt.

Literature.

DISEASES OF THE LIVER. (a)

OF an Italian historian and antiquary of the last century it was observed that his works contained "something that was new, much that was useful, and everything that was superfluous;" and the same judgment may be passed upon the present volume, which might have been advantageously contracted to one-half its present size. The author begins with a chapter on spelling reform, in which he enthusiastically advocates the phonetic system. He states that he would have had his work so printed but for the fear of troubling foreigners, by whom his books are so much read. We regret that we cannot fall in with Dr. Harley's view of a product so essentially evolutional as language and spelling. Some little changes our Transatlantic cousins have introduced, such as "center" for "centre," and "honor" for "honour," but these were the ordinary English spellings before the time of Dr. Samuel Johnson, who has much to answer for in this respect. If the English or any other language were remodelled phonetically it would make matters worse even than at present. Dr. Harley's chapter on champagne is truly remarkable. He says (p. 251): "All my champagne I import myself, and, as my personal friends know, it is A 1." Although not having the honour of being one of this favoured circle, we heartily endorse the statement. Dr. Harley, however, runs full tilt at the "très sec" champagne, so much favoured in these countries, asserting that it is merely vinegar disguised, and that it is most unwholesome. This opinion has made us positively unhappy, and, since we read it, has haunted us like the skeleton of the Egyptian feast. We like our two glasses of "très sec" at dinner, and they agree with us. We now take them with a guilty conscience, and have been afraid to try them with litmus paper, as Dr. Harley says he did with an unhappy patient, who, he adds, passed a sleepless night in consequence. As for the 40s. brut champagne, our author says he would add the letter *e* to the word brut to describe it. We agree with him, and regret that this particular product was not included in the second schedule of the Sale of Poisons Act. It does not appear whether Dr. Harley approves of the sweet champagne used in Russia. We do not: acid may be bad, but acid muffled up with sugar is worse. Generally speaking, Dr. Harley's book is a good, conscientious record of close and extended clinical work. It is diffuse, but full of valuable matter. It is the production of a man who has worked hard himself and read up the work of others. In his title-page he quotes the wise maxim that "true science is the key of wise practice;" and it is therefore to be regretted that some of his physiology is that of his youth, and scarcely up to the modern standard. He speaks of blood corpuscles escaping from their coverings. He gives a list of germicides; and while mentioning salicylic acid, omits salicin. In the spectroscopic examination of icteric urine (p. 700) he follows the method of Stokvis, of Amsterdam, who treats the urine with a little zinc chloride, and then with an excess of ammonia. This mixture shows a characteristic appearance, but is, however, open to the same objection as the spectroscopic examination of Gmelin's test, recommended by MacMunn, of Wolverhampton, in his admirable treatise, "The Spectroscope in Medicine," a second edition of which is so much called for. A much simpler qualitative and (to a certain extent) quantitative test of icteric urine is given in the "Proceedings of the Royal Irish Academy," 2nd Series, vol. iii. (Science); and this is not even mentioned by Dr. Harley. He can, however, hardly be blamed for not having noticed a test published in the proceedings of a scientific and non-medical society, in doing which we think its author did not exercise a wise discretion. All these points are very slight drawbacks in a really valuable book. It is diffuse; but this very diffuseness renders it chatty and amusing, and it teems with anecdotes and *bonhomie*. The reader having taken the volume up, does not care to lay it down; and there is no one who will not have his knowledge improved by perusing it. It is beautifully got up, has many fine illustrations, including chromolithographs, and an exhaustive index.

◆

DR. GRAILY HEWITT'S DISEASES OF WOMEN. (a)

We are much pleased to welcome a fourth edition of Dr. Graily Hewitt's well-known work on Diseases of Women. As the title page tells us it is revised, enlarged, and in great part re-written. Ten years is a long period of time in this rapid age, and it does not fall to the lot of many authors to review their ten-year-old works and find occasion merely to amplify and accentuate, and not to overturn in order to begin anew. It is now ten years since the last edition of our author's book appeared, and during the whole of this long interval Dr. Hewitt has been an attentive observer, and if he has generalised, it cannot be said that he has done so without reason. In the introduction he says, "The conclusions expressed ten years ago have been tested and verified by subsequent experience."

The part that is peculiarly our author's own is the extensive and widely ramifying subject of uterine flexions. On this subject he states, also in the introduction, "I have explained (in the present edition), to my own satisfaction at all events, how and why it is that changes in the shape and position of the uterus are so liable to occur; what, in short, are their predisposing causes." "Alterations in the shape and position of the uterus are rarely witnessed, except in individuals whose general health has become seriously impaired by a systematic, and often a lengthened, practice of taking little food. The term 'chronic starvation' appropriately designates this condition; and a long course of observations has convinced me that it is a most important factor in the production of the class of diseases above alluded to."

Every one acquainted with Dr. Hewitt's writings will expect that flexion and displacement of the uterus will be the most prominent subjects of the work, and they will not be disappointed, whilst the last quoted sentences will show the direction in which his observations have led him to look for their causes. He leads us one step further back towards their prime cause; but has he really named the prime cause itself? Every student of gynæcology will know that numbers of patients suffering from these affections cannot be made to eat, and more will have made the observation for themselves, that the patient who has the best healthy appetite is the quickest out of their hands. But which is the first cause, the uterine affection or the starvation? We should be inclined to conclude from other parts of the work before us that if starvation originates flexions and displacements, these latter themselves are no less powerful factors in producing the anorexia that leads to the starvation.

Dr. Hewitt plainly attaches immense importance to these two conditions, to him they play a not inconsiderable part in a surprising number of ailments. We have already made our readers acquainted with his views on the relationship between these conditions, and the persistent vomiting of pregnancy (*Medical Press and Circular*, pages 510, 535; 1882).

With regard to their relationship to uterine pathology generally, he laid down the following three propositions in his edition of 1872:—

1. Patients suffering from symptoms [of uterine inflammation] (or more properly from symptoms referable to the uterus) are almost universally found to be affected with flexion or alteration of the shape of the uterus, of easy recognised character, but varying in degree.

2. The change in the form and shape of the uterus is frequently brought about in consequence of the tissues of the uterus being previously in a state of unusual softness [or what may be often designated as chronic inflammation].

3. The flexion once produced, is not liable to perpetuate itself, so to speak, but continues to act incessantly as the cause of chronic inflammation present. Pp 62 and 63.

Since that time nothing has occurred to shake my confidence in the substantial truth of the conclusions just stated; I have had, on the contrary, more reason than ever to be satisfied of their accuracy. The parts enclosed in brackets, and which refer to "inflammation" alone, require to be altered, as I have now a more complete and satisfactory explanation to give of that condition alluded to as "softness."

He then goes on to explain what he means by the term "inflammation," as mentioned above, and to point out what appears to him to be its cause. He says: "The uterus is very liable to fall into a state of passive congestion when it has become distorted and bent upon itself, though it may become congested from other causes.

"2. The uterus is very much more liable to become distorted when its tissues are in a soft, flaccid condition.

"3. Softness and flaccidity of the uterus generally indicate mal-nutrition of the organ.

"4. The so-called chronic inflammation is generally chronic congestion the result of flexion of the uterus" (p. 64).

The remark of Scanzoni that "the so-called chronic inflammatory changes in the uterus should be more correctly looked upon as chronic nutrition-disturbances," was the hint, as he acknowledges, that led him, after careful examination, to the above-mentioned conclusions.

Our author's theory, then, is briefly this—that semi-starvation leads to softness and flaccidity of the uterus (and appendages), that these lead to form- and position-changes in the uterus, and that these in turn lead to "the large majority of the discomforts, pains, and inconveniences complained of by patients and referred by them to the generative organs." Amongst the ailments mentioned by our author as directly caused or influenced for evil by these alterations of form and position are congestive hypertrophy—acute congestion he claims to be identical with the irritable uterus of Gooch (p. 79)—subinvolution (p. 87), local atrophy (p. 89), endometritis (p. 110), fungous condition of lining membrane of uterus (p. 115)—exemplified in a most interesting case reported on p. 113, nausea and vomiting in non-pregnant as well as pregnant women (p. 354), pain over sacrum, by the side of umbilicus, or in the groin (p. 223), dyskinesia (*ibid.*), dyspareunia (p. 224), dysmenorrhœa, leucorrhœa, menorrhagia, amenorrhœa, sterility, abortions, disturbances of function of bladder and rectum, reflex nervous (hysterical) symptoms (pp. 224-5), eversion of cervix (p. 220), erosion of mucous membrane of os (p. 381).

From the preceding we see the immense importance attached to these conditions by Dr. Hewitt, and although doubtless many able gynæcologists will dissent from some or even many of his conclusions, we would venture to assert that they will in the main be accepted as correct the more readily, as the affections in question are studied at the bedside, without prejudice, in the light thrown upon them by our author. It is quite true that he has not succeeded in demonstrating pathologically the accuracy of his views, and in many instances clinches the diagnosis, so to speak, by the results of treatment, but it is equally true that pathological demonstrations *post mortem* are almost impossible, for the sufferers do not often die of these diseases. Under the circumstances, then, when the best light in which to study the etiology of the great mass of uterine diseases that can be obtained comes from treatment, a physician is perfectly justified in making use of it. Neither can it be said that such light is very imperfect and insufficient, when the treatment is always successful, or only fails in a few instances, in which the failure can be satisfactorily accounted for, without damage to the theory.

(a) "The Pathology, Diagnosis and Treatment of the Diseases of Women." By Graily Hewitt, M.D. Lond., F.R.C.P. Fourth Edition; revised, enlarged, and in great part re-written. London: Longmans, Green, & Co.

Dr. Hewitt is a firm believer in the uterine origin of the so-called hystero-neuroses. He says (p. 549): "In these cases the uterus is in a condition of what may be termed traumatic congestion—the blood current is forcibly arrested in the tissues of the uterus. The common cause of such arrest in these cases is compression of the organ at its centre, by the bending or flexion of the uterus." In support of these views he adduces a series of eighteen cases arranged in chronological order observed by him in the ten years from 1870 to 1880. In six of the cases the uterus was retroflexed, and in twelve it was anteflexed. In all the cases cure or great relief was brought about by redression of the displacement. The records do not tell us what (if any) other treatment was adopted in these cases.

When he acknowledges that the phenomena denominated hysteria are sometimes met with in males, he would probably also agree with Landau (*Deutsche Med. Zeitung*) when he says, "In vain have people sought for the causes of the hydra-headed hysteria in disease of one organ, first, as the name indicates, in the uterus, then in the ovaries, especially in the left." Freidreich, of Heidelberg, drew attention to the part the clitoris and the pubic nerve play in the originations of so-called hysterical manifestations, and succeeded in curing eight cases of the affection by vigorous cauterization of the much-abused appendage. We would say with Landau, that those who look upon disease of any one organ as even the main cause of hysteria look upon the affection with too narrow a view. Legrand du Saulle, the most recent writer on the subject, expresses views that will meet with acceptance from most physicians, when he styles hysteria a general neurosis, that may be called into play by almost any physical or psychi-excitant. Dr. Hewitt would be the last to claim for flexions of the uterus an exclusive part in the origination of the phenomena under discussion, or even a near approach to it; at the same time, however, we think that the book before us places too low a value upon, or passes over altogether, many other of the factors that may be concerned in the manifestations of hysteria.

The chapter on the natural history of the uterus and ovaries, if not so full as that of some authors, is nevertheless clear and concise. That on lacerations of the cervix uteri, and the method of treatment to be adopted in such cases is in no way behind the times.

The distinction between prolapsus uteri and supra-vaginal elongation of the cervix is accurately pointed out, as first drawn attention to by Huguier. He does not allude to the part played by the muscular structures of the vagina, by grasping and dragging down the lower segment of the uterus, whilst the fundus remains fixed, in the production of this form of disease.

In the chapter on diseases of the Fallopian tubes a slip of the pen occurs. He says: "Tumours constituted by distension of one or both tubes are . . . . accompanied by closure of *one* or *both* extremities of the tube" (p. 681). If both ends of the tube were not closed, it would be difficult to comprehend how a closed cavity could be formed, and if the cavity were not a closed one it could scarcely form a tumour "constituted by distension," as if the fluid did not flow out at one end it would at the other.

In the excellent chapter on fibroid tumours of the uterus the remark occurs, "they are found equally in the single and the married." This may be true strictly speaking, but we would add that as a rule the large fibroids occur in women who have not borne children. This statement seems borne out by the author's own tables. Thus, an analysis of the one on pages 624 and 625 shows us that fourteen women suffering from polypi had borne a total of 52 children, whilst of thirty-two women the possessors of fibroids as large as a small orange but six had borne children, viz., three had had one each, one had had two, one three, and one four; so that the whole of the thirty-two had had but a total of twelve.

In the chapter on cancer of the uterus we are pleased to observe that even in cases that are hopeless Dr. Hewitt is not in favour of doing the patient harm by telling her of the hopelessness of her condition, for scarcely anything is more calculated to shorten life than to destroy all a sufferer's hopes of living.

The remaining chapters are well written and thoroughly trustworthy, and we can safely say of the whole work that it is eminently calculated to be of service to every student of gynæcology, whether already practising or about to practise.

An appendix of seventy pages goes thoroughly into the differential diagnosis—A, of pains referable to the internal generative organs; B, of pelvic tumours and enlargement of the uterus, including pregnancy; C, of abdominal tumours; and D, a discussion of the subject of virility in man and of sterility in the female.

The work is well got up, singularly free from errors, and reflects great credit on the publishers, Longmans & Co.

The illustrations, many of which are new, are excellent. Most of those representing flexions and displacements of the uterus are life size, and the various mechanical appliances for their relief "are drawn the actual size of the instruments, with a view of rendering the descriptions and directions for treatment more explicit and less liable to misinterpretation."

◆

CHOLERA. (a)

This *brochure*, so opportunely appearing at the present moment, is a reprint of a paper read before the meeting of the British Medical Association held in this city in 1867. At that time we had passed through an outbreak of cholera, and the author gives carefully and well-taken notes of 20 typical cases selected from a large number of patients treated during that epidemic. Mr. Little wisely expresses his belief that drinking-water is a great source of infection; and gives a very interesting instance, occurring in Kingstown, where the cholera went from one house to a second, and from that to a third, these three houses being situated on a slope, and the first being the highest. Kingstown is now supplied with Vartry water, but then depended on pump-wells, which were shallow, the town being built upon granite rock with a thin covering of earth. The disinfecting substances used with the evacuations were recognised in the three wells, evidently showing that the disease was thus propagated among houses which had no other means of communication. Mr. Little is, of course, a believer in the communicability of the pestilence—as, indeed, every one is now in regard of a malady which always runs along the beaten paths of commerce. The cases are very briefly but clearly put together, and the treatment is good, the author making extensive use of mustard—a most useful drug for cholera. Of course, the ordinary table mustard is not reliable, and we are recommended a strong tincture of mustard, a uniform and dependable article. There is no feature in cholera more formidable than the agonising cramps of the abdomen and of the limbs; and it is to be regretted that the author does not notice the complete relief obtainable by strong and repeated doses of hypodermic morphia pushed until the pupils begin to contract. In addition to completely subduing the cramps, it was noticed in the last cholera epidemic in Constantinople that this treatment exercised a very mitigating influence upon the nervous and vaso-motor symptoms, and was not without effect on the diarrhœa. We believe, also, that there is a future before the intravenous injection of warm water, or of salt and water. A retrospect of the cases is given in five tables, which regard them in different points of view. These tables show that the drunkard, or the man of irregular habits, has but little chance in a cholera epidemic; and equally so he who lives in a dwelling with bad hygienic conditions. On the other hand, those who live soberly and regularly, in proper dwellings, and who eat, drink, and avoid what they ought, are practically safe. If, in addition, they provide themselves with simple preventive remedies, so that they can at once grapple with the early symptoms of the disease, this immunity becomes complete. Mr. Little's essay is an interesting and valuable one, and gives an amount of practical information not always found in more pretentious volumes. Any one who wishes to quickly make up the subject could not do better than read it.

◆

DUNCAN'S CLINICAL LECTURES ON DISEASES OF WOMEN. (b)

The author tell us in the preface that the present edition contains sixteen new lectures "not including appendices which are additional matter, differing from the lectures chiefly in form. . . . The lectures are called clinical, not because they are strictly speaking such, but because they are so to some extent, and because they are not systematic. . . . The lectures do not aspire to completeness, being clinical, not systematic."

(a) "Cholera." By P. C. Little, F.R.C.S.I., L.M. Medium 8vo., pp. 37. London: John Churchill & Sons. Dublin: Fannin & Co.

(b) "Clinical Lectures on the Diseases of Women." By J. Matthews Duncan, M.D., LL.D., &c., President of the Obstetrical Society. Second Edition, much Enlarged, with Appendices. London: J. and A. Churchill. 1883.

The title page gives us no indication of what is told us in the above extract. The lectures are really "Lectures on *some* of the Diseases of Women." Without taking this explanation into consideration the work before us is an anomaly. It is addressed to students, yet contains but little of the fundamentals of the subject it treats on, and scarcely anything in a systematic form. Looked at as a collection of clinical lectures to students, the volume will prove disappointing, but if each lecture be looked upon as a unit all cause for disappointment will vanish. Everyone acquainted with Dr. Matthews Duncan's writings expects to find in whatever he presents to the public, new points of view offered, new subjects for thought, even although the subject treated of may be trite, well worked, and, to all appearance, exhausted. He expects to find everything laid down in vigorous, concise language, the meaning of which will be unmistakable. He expects to find, moreover, an appreciable quantity of humour, lending piquancy here and there, humour often of a somewhat grim kind it is true, but for this very reason characteristic of its author. The expectations of such an one will not be disappointed in the work before us. It is entertaining as well as instructive, so that the perusal of it has been not a task but a pleasure. The language, as we have hinted it would be, is vigorous, and never more so than when the author is attacking the theories of some who think differently from himself. His language has indeed, occasionally too much vigour, as for instance in the following passages. Speaking on some of those forms of uterine disease that occupy an exceedingly large space in some gynæcological text books he says, page 418: "The whole of this special uterine pathology I reject as being meantime at least, unworthy of any place in medical writing."

In the chapter on "Remote or Indirect Symptoms," he says in the same strain: "Looking into popular gynæcological manuals you will find this protean group" (of symptoms) "around split cervix, displacement, ulceration," &c. A great author and practitioner describes retroflexion of the uterus as producing, or as having for symptoms, dysmenorrhœa, menorrhagia, leucorrhœa, abortion, sterility, obstruction of rectum, ribbon stools, pain in defæcation, intestinal paralysis, disturbance of digestion, flatulence, pyrosis, nausea, disorder of liver, disordered secretions, hysteria, intellectual disturbance, and many, many, more. All these may accompany retroflexion, no doubt, but they are in no sense symptoms. You will utterly reject all this kind of pathology as worse than useless, and examine the matter more narrowly."

We think such language as this is unnecessarily strong. These theories upon which Dr. Matthews Duncan pours out the vials of his wrath may not be altogether reliable; very few we suspect will accord to them the importance they claim from their originators, but that is far from saying that they are to be utterly rejected as being "unworthy of any place in medical writing." Some views again so contemptuously cast aside by our author still hold a place in the estimation of all the leading gynæcologists of Great Britain, the Continent, and America, and will perhaps continue to do so notwithstanding the denunciations hurled at them in these pages. As we have already intimated, the lectures as units will meet with approbation. The chapters on Missed Abortion, Abnormal Pelvis, Retention of Mucus, Hydroperitonæum, Spasmodic Dysmenorrhœa, being specially worthy of mention. Whilst those on Open Fallopian Tube and Cervix Uteri, on Spontaneous Dilatation of the Virgin Uterus, Intra Uterine Menstrual Coagula, &c., being work on newer ground will not fail for this reason to claim their share of attention.

◆

THE MEDICAL BILL.

We regret to understand that, as we write, the Bill is in extreme peril, and, before this reaches our readers, it may probably have been withdrawn for this Session. For the last week a very strong opposing deputation from the Edinburgh and Glasgow medical Corporations has been in London seeking to increase the corporate representation on the Scotch Medical Board. The delegates are Dr. Haldane, Dr. Scott Orr, Dr. Patrick Heron Watson, Dr. George W. Balfour, Dr. MacVail, and Dr. Peddie, and they have, we believe, secured the support of Mr. Waddy, M.P., Mr. Dick Peddie, M.P., and other leading Scotch members. From Ireland the Colleges are represented by the President of the Royal College of Physicians, Dr. W. Moore, and Dr. J. W. Moore; Mr. Wheeler, President of the College of Surgeons; Mr. MacNamara, Dr. Hamilton, and Dr. Jacob. The Bill is blocked by Col. King-Harman on behalf of the Irish Colleges, and Mr. Waddy for the Scotch bodies, and, unless these blocks be taken off, the second reading cannot, according to the rules of the House, be taken after 12.30 at night. The Bill is down third on the notice-paper for Tuesday, but, as the first order is the Appropriation Bill—upon which it is expected that the leader of the Opposition will have something to say—and the second and third orders the Agricultural Holdings Bills, which will give rise to debate, it is almost certain that the Medical Bill, which stands fourth, will have no chance of coming on at all. On Wednesday (to-day) the Indian Budget will occupy the entire sitting; and save the slender chance of a second reading on Thursday and Committee on Friday, all hope of the Bill is gone for this year.

We must express our extreme regret at this condition of affairs, and our belief that the Bill would undoubtedly have passed before this if Mr. Mundella, when he received the measure from Lord Carlingford, nearly three months ago, had dealt with it in a different way. If he had insisted, as he might have done, on its being put at the top of the notice paper for any one evening of that period, it would not have been in the power of any opposition to stop it, and if he had consented to listen with good temper and in a conciliatory spirit to the reasonable remonstrances of opposing bodies, there would have been no serious opposition.

While we have supported the Bill in principle and in its purpose with all our power, we have been quite unable to see that it was anything but a very defective method of dealing with a great subject, tolerable only as a step in the right direction, and as establishing a principle. The measure would seem to have been dictated by one mind, and that mind inexperienced in medical politics and incapable of looking beyond its own area of feelings and prejudices, and, consequently, the Bill bristled with matter which clearly the Scotch and Irish Corporations could not permit to pass. The salient fault of the Bill was that it sacrificed those bodies which, if they were not worthy of admiration, were at least to be feared as opponents to the University interest and—without any justification whatever on educational grounds—put the whole medico-educational world under the feet of the Univesities. The Bill was radically vicious in that it was constructed upon the assumption that a *soi-disant* University must necessarily be something altogether superior to a medical corporation, a theorem for which there is not a shadow of basis. There are Universities and Universities, as there are Corporations and Corporations, and we do not hesitate to assert that sundry of the Universities exalted by this Bill are, in all respects, educational, academic, and medico-political, beneath several of the Corporations.

These faults of the Bill might have been remedied without sacrifice of principle, or of the public interest, by a minister who was willing to listen to reason, and to give a polite answer to fair remonstrances, but, unfortunately, when the Bill left Lord Carlingford's hands, it passed into those of a minister who was not prepared to descend to this method of treating a legislative difficulty. Mr. Mundella seems to have decided either to force the Bill forward without material change or lose it, and, as was inevitable under such a policy, he hast lost it. We repeat that we deeply regret that it is so, because it will necessitate the re-opening of the reform agitation, and of the contest through which medical opinion has passed. Next year, and every year, we shall have a Bill constructed on the same excellent principles as this measure, but, let us hope, less open to objections of detail and less unjust to the medico-educational institutions of our country. We believe we know the feelings of these institutions sufficiently well to be able to say that they will not resist a reasonable reform which does not altogether sacrifice them to other not more meritorious institutions; and when we get a Bill which effects such a reform, it will certainly pass without serious resistance.

◆

THE IRISH UNION OFFICERS' SUPERANNUATION BILL.

We cannot help expressing our disappointment and even disgust in announcing the fact that this Bill has probably been lost for the present. The Irish Medical Association has been represented in London for the past week by Dr. Jacob its President, and the Union Officers' Association by Messrs. Cope, Atkinson, and Molloy. The Bill, having got through its second reading last week after severe opposition by a section of the Irish Party, was down for the Committee state on Saturday night. It would have had the combined support of the Government and every section of the House save three or four Irish Members, but these members blocked it, and, in order to prevent its being considered, they obstructed the Committee of Supply until Lord Richard Grosvenor—the Government whip—was obliged to postpone the Bill until Monday. On that evening the same tactics were adopted until the hour of 12.30 midnight, when the measure, being a blocked order, had to be again postponed. On Tuesday it stood far down on the list, and was practically postponed for the Session.

For this catastrophe our poor-law medical brethren have to thank Messrs. Biggar, O'Kelly, Leamy, and Lalor, and also the state of public business which caused the measure to be delayed until the end of the Session.

We deeply regret the matter, but are not in the least discouraged. The ultimate success of the measure is only a question of time and steady persistence by its promoters.

◆

Notices to Correspondents.

The Students' Number, 1883-84.—The annual educational number of this Journal will be published on Wednesday, September 19th. Deans, Registrars, and others connected with the various medical schools throughout the United Kingdom, will oblige by forwarding the latest prospectus and such other information as will assist the Editors in the compilation of this important number.

Mr. Robertson.—White agaric has been introduced as a reliable purgative; to obtain successful results by its use it must be given in considerable quantity, about twenty grains of the powder being a moderately large dose. In small doses it is astringent, and has been found of service to check the night sweats of phthisical patients, and diarrhœa. The dose of the extract is three to six grains; of the alkaloid agaricin, one-twelfth to one-sixth grain.

K. E. F.—The most noteworthy points were mentioned in the diagnosis, but the treatment recommended did not succeed in controlling the paroxysm, which gradually subsided as attention was diverted from the prominent symptoms. It can hardly be regarded as an altogether successful experiment.

Dr. Andrews.—The status of practitioners possessing other than English diplomas, in so far as it remains to be yet more distinctly defined, will probably depend in a great measure on the impression created by the deputation of foreign graduates which recently urged its grievances before the notice of the Vice-President. We do not endorse your representation of the matter.

Dr. Storey.—Except under a warrant issued by the coroner, you cannot compel the friends to grant a post-mortem examination. The law fails to recognise any legitimate scientific curiosity in this respect, and is indeed emphatically obstructive.

Dr. Connell. — There is every reason to expect that when this reaches you the fate of the Bill will be decided, the second reading of the measure being arranged for on this day (Tuesday). As far as we are able to discover, no such amendment as that you name is to be introduced.

Dr. Rawson.—Free use of the exploring needle as an aid to diagnosis is now a very generally recognised proceeding, but a good many physicians still hesitate to adopt it in many cases where, by the reasoning of others, it might be advantageously introduced. In chest affections it may be appropriately and safely utilised.

Mr. Farnleigh.—It should be pushed to a considerable degree to be successful. Twenty-grain doses at intervals such that two or two and a-half drachms are taken each twenty-four hours is not too much.

Mr. Greenwood.—Thanks for the information.

Mr. J. Aston.—The evidence of collusion, although suspicious, was not sufficiently conclusive to warrant his removal from the Register. The person referred to was called before the Council and admonished as to his future conduct, and there the matter ended. You will see an account of the proceedings on reference to our numbers for May last.

L.R.C.P.—Your case, which as a young practitioner you consider unique, is another illustration of the adge that "there is nothing new under the sun," in fact, the complication is one common to the disease in its acute form. The treatment pursued, after reference to "Naphey's Modern Medical Therapeutics," was the only rational proceeding, and must have convinced you of the propriety of relying upon the experience of your seniors in cases of serious moment.

◆

Vacancies.

Cashel Union, Cashel Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, September 1.

Central London Ophthalmic Hospital.—Assistant Surgeon. Applications to the Secretary on or before September 8.

General Infirmary, Gloucester.—House Surgeon. Salary, £100, with board. Applications to the Secretary before September 1.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident Clinical Assistant. Applications to the Secretary on or before September 1.

Jersey Public Lunatic Asylum.—Superintendent Medical Officer. Salary, £250. Applications to the President of the Committee before September 1.

Liverpool Royal Southern Hospital.—Senior House Surgeon. Salary, 100 guineas, with board. Applications to the Chairman of the Medical Board before August 27.

London Hospital.—Demonstrator of Practical Chemistry. Salary, £100, and a proportion of fees. Applications to the Warden before September 1.

Sheffield.—Medical Officer of Health. Salary, £500. Applications to the Chairman of the Health Committee before September 6.

St. Bartholomew's Hospital.—Assistant Physician. Applications to the Clerk before September 11.

Thomastown Union, Graigue Dispensary.—Medical Officer. Salary, £100, and fees. Election, August 23.

Births.

Fletcher.—August 14, at Soham House, Highgate, the wife of Geo. Fletcher, M.D., M.A., of a daughter.

Flint. — August 14, at Westgate-on-Sea, the wife of A. Flint, L R.C.P. Lond., of a son.

Green.—August 8, at 116 Stricklandgate, Kendal, the wife of T. Beaufoy Green, M.R.C.S. Eng., of a son.

Hill.—August 11, at Oak House, Tufnell Place, Holloway, the wife of J. R. Hill, L R.C.P., of a daughter.

Hockin.—August 14, at Southport, Queensland, the wife of C. Treverne Hockin, M.R.C.S., L.R.C.P., of a son.

Smith.—August 9, at 1 Bertie Terrace, Leamington, the wife of Francis William Smith, M.D., of a daughter.

Tweedy.—August 16, at 2 Gardiner's Row, Dublin, the wife of H. C. Tweedy, M.D., of a daughter.

Marriages.

Cheesewright—Snelling.—August 15, at St. John's, Lewisham, John Francis Cheesewright, M.R.C.S. Eng., of Rawmarsh, Yorks, to Louisa Georgiana, second daughter of the late Joseph Snelling, of St. Mary's Cray, Kent.

Ferguson—Irvine.—August 8, at Mossley Hill Church, Liverpool, Thomas Leslie, only son of the late James Chambers Ferguson, M.D., to Eleanor Jane, daughter of the late George Irvine, Brucklay House, Mossley Hill, Liverpool.

Lory—Alford.—August 14, at Mangotsfield, William Manley Lory, Surgeon R.N., eldest son of Charles Marsh Lory, of Staple Hill Lodge, near Bristol, to Florence Bertha, younger daughter of the Rev. George Alford, Vicar of Mangotsfield, Gloucestershire.

Peck—Owen.—August 11, at the Church in Gordon Square, Awdry Peck, B.A. Oxon., L.R.C.P. Lond , M.R.C.S. Eng , of 37 Torrington Square, W.C., to Ethel, eldest daughter of David Henry Owen.

Thorpe - Marsh.—August 8, at St. George's, Sheffield, George E. Knight Thorpe, M.R.C.S., Sheffield, son of the late G. B. Thorpe, F.R.C.S., of Staveley, Derbyshire, to Edith Anne, younger daughter of the late Theophilus Marsh, of Sheffield.

Wagstaffe—Tetley.—August 8, at All Saints', Branksome Park, Bournemouth, William Warwick Wagstaffe, B.A., F.R.C.S., late of St. Thomas's Hospital, to Helen Mary, daughter of the late Francis William Tetley, Esq., of Fox Hill, Weetwood, near Leeds.

Deaths.

Arrott.—August 13, at Almond Bank, Perthshire, James Arrott, M.D., late of Dundee, aged 76.

Burrows.—August 6, at his residence, Riverstown, co. Sligo, Thomas Burrows, M.D., aged 73.

Harrisson.—August 11, at Gunnersbury, Henry Harrisson, M.R.C.S., late of Upper Montagu Street, W., aged 72.

McOscar.—August 8, at Argyll Street, Regent Street, John McOscar, M.D , aged 56.

Price.—August 12, at Lower Pembroke Street, Dublin, John Robert Price, M.D., aged 94.

Southby.—August 10, at Bulford House, Wilts, Anthony Southby, M.D., aged 83.

WIESEN AS A HEALTH RESORT IN EARLY PHTHISIS, WITH DIRECTIONS FOR CLOTHING, DIET, AND EXERCISE IN THE SWISS ALPS DURING WINTER.

By A. T. TUCKER WISE, M.D.,

Formerly Visiting Physician to the Infirmary for Consumption, Margaret Street, Cavendish Square.

(*Continued from page* 155.)

Chapter V.

Winter Clothing.

The selection of suitable clothing for an Alpine climate will contribute greatly to health as well as to comfort.

The first advice tendered to ladies who seek restoration to health from lung disease is :—Abandon corsets absolutely, and wear the loosest cincture on the waist. This injunction cannot be emphasised too strongly. One prominent sign of what may be termed "cure" of phthisis, at high altitudes, is the almost invariable expansion of the whole or portions of the chest walls. To impede such a beneficial result is to limit the advantages of breathing mountain air. No one could wittingly be guilty of such an irrational procedure as to curtail the actual physical improvement they travel many miles to secure. Yet usually whilst the upper regions of the chest are allowed free play, the most mobile section, the diaphragm, is fettered and confined in its movements by an unyielding investment pressing on the abdominal viscera. In this way an opposite conformation is maintained against what physiology and common sense would indicate ; for in many instances where damage exists in the superior thoracic regions, limitation of movement is desirable in *these* situations, rather than in the lower and sounder parts of the lung.

The substitute for corsets should be a thick flannel waistcoat or jersey. Flannel should also be worn next the skin over the trunk and extremities. Chamois leather may be substituted when over-sensitiveness of the skin renders the use of flannel unbearable ; generally, however, a fine texture can be procured which is not too irritating. A good stock should be taken as frequent changes are beneficial.

The coverings for the feet and legs require attention. In all cases woollen socks or stockings are indispensable. Flannel pants should be made long enough for socks to be drawn over them. By enveloping the whole body in flannel the patient is spared the necessity of loading the exterior with thick weighty dresses or heavy overcoats, which fatigue the wearer and confine the act of respiration. Those who are liable to suffer from cold feet or are susceptible to chilblains will find thick worsted socks and cloth gaiters a necessity. As a prophylactic against chilblains, bathing the feet in salt and water, avoiding tight boots, and changing the socks whenever the feet are damp from perspiration, &c., will carry many through the winter of a cold climate, who might otherwise suffer much inconvenience and pain from these minor but troublesome ailments. Boots should not be over thick and heavy, which renders them inelastic. There is no utility in having clump soles, as leather gets saturated quickly with moisture and takes a long time to become thoroughly dry. Ordinary stout skating boots with broad toes, low heels, and plenty of room inside them, which may be filled up with a cork sock, are suitable both for ladies and gentlemen ; they should be well greased every day and always changed immediately after a long walk. Goloshes are useful for short journeys, but cannot be recommended for constant use on account of confining the prespiration. All clothes should be light in colour, as near grey as the taste will allow. A light colour does not absorb nor radiate heat so much as black, therefore a wearer of grey will be comfortably free from the heat of solar radiation and warmer in the shade. Waistcoats should be lined in the back with flannel, as with modern garments all the protection is in front of the body. With double-breasted apparel a man may have from ten to thirteen thicknesses of woollen clothing in front of him, whilst his back is covered with three layers of wool only. If men endeavoured to dispense with the use of braces greater play would be given to the muscles of inspiration. Hats may be of straw for the sunny weather, but light-coloured thin felt answers very well. Furs should not be worn when taking exercise. The ladies' fur tippet can be discarded as dangerous at any time, from the fact of its covering the shoulders only, causing that part of the body to become overheated, and therefore liable to chill. A short list is appended of articles found to be serviceable for these climates :—

One fur or railway rug. One warm ulster with hood or fur-lined coat for travelling or sleighing. One thin overcoat, a Shetland shawl. Two suits of clothes (waistcoats lined). Thick flannel vests and flannel shirts. Flannel night-shirts. Half-a-dozen or more worsted socks. Flannel pants. Cloth or fur gloves with gauntlets. Cork socks. A pair of dark neutral tint spectacles. A few rough bath towels and a flesh glove. One woollen muffler. Two pairs of stout boots (one pair smooth for skating, the other with a few spikes in the soles, not thickly studded with nails, or the snow will ball on them). A pair of leggings are required for "coasting" unless long boots are taken. One pair of shoes or thick slippers with heels, can be worn indoors with spats over them. Bootlaces, dubbin, and skates may be added, and for ladies, a sunshade and goloshes with or without cloth tops. A fur foot-warmer or large fur-lined boots are also very useful.

Chapter VI.

Diet in the Swiss Alps.

The food at St. Moritz, Davos, and Wiesen, as almost every where in Swiss hotels, consists largely of azotized or nitrogenous matter. Many who have visited Davos, for example, will recollect that much lean meat is eaten, whilst the proportion of animal fats is very small.

It is essential to the health and well-being of individuals that a proper proportion of nitrogenous and non-nitrogenous food should be consumed. The latter consists chiefly of starch, fats, sugar, saline substances, and water, which in the ordinary way with meats, form the mixed dietary most suitable for man; as the structure of his teeth and past experience indicate. But whilst an almost exact estimate can be formed of the elements necessary for the system to ingest, it must not be forgotten that the quantity and kind of food taken will depend very much on the condition or idiosyncrasy of the consumer. As a general rule, few delicate persons would be capable of effectually digesting the quantity of bread, pastry, milk, and root vegetables, &c., which would be requisite to constitute with the meat eaten, a fair combination of nitrogenous and non-nitrogenous matter, and as there is a marked absence of palatable fat at these places, a little consideration of the means for balancing the needful combination, will conduce to the recovery of health and avert many ill-effects arising from perverted nutrition—as dyspepsia, troubled sleep, a loaded tongue, vitiated secretions, &c.

"Many people," Dr. Pavy remarks, "seem to look upon meat almost as though it formed the only food that really nourished and supplied what is wanted for work. The physician is constantly coming across an expression of this view."

The greatest importance must be attached to the use of fats during winter in the Alps; for it is well-known that the inhabitants of Siberia, Greenland, &c., and all cold countries, eat enormous quantities of these heat-producing materials, without which they would be unable to resist the intense cold of their frigid climate. Sir John Ross observes—"It would be very desirable, indeed, if the men could acquire the taste for Greenland food, since all experience has shown that the large use of oil and fat meats is the true secret of life in these frozen countries."

Dr. Cheadle also lays much stress on the value of fats in cold climates. "One effect of the cold was to give a most ravenous appetite for fat. It is the most valuable part of food in winter, and horses and dogs will not stand work in the cold unless fat." (*a*)

Besides forming the chief articles of diet which are required for a calorifacient or heat-producing agent, they may almost certainly supply a pabulum for the oxidising process of fever in phthisis, to act upon, thereby, not only restricting the waste of tissue in that process, but perhaps in some way diverting its occurrence, as is witnessed when cod-liver oil is taken. With an increase in animal food, which can be readily eaten at high cold levels, the appetite being sharpened by exercise and low temperature, the necessity for fats is by no means abated, on the contrary, a physiological demand is created for additional food capable of undergoing the process of oxidation, which cannot be wholly supplied by the lean meat or by starchy and saccharine bodies.

"It appears from the experiments of Pettenkofer and Voit that increasing the proportion of nitrogenous matter in the food determines an increased absorption of oxygen by the lungs. Nitrogenous matter it is which starts the changes occurring in the system, and the suggestion presents itself that upon the amount of nitrogenous matter may, to some extent, depend the application of oxygen to the oxidation of fatty matter. Under this view the success of Mr. Banting's system may be due, not exclusively to the restriction of the principles that tend to produce fat, but in part, also, to an increased oxidising action promoted by the large amount of nitrogenous matter consumed." (Pavy).

Let us draw atrention to the substances at these health resorts that furnish the calorifacient group of alimentary principles. Disregarding the fat produced by a complicated metamorphosis of the carbo-hydrates and a small part of the nitrogenous food ingested, (*b*) the main articles of diet from which fat is derived, would be butter and milk. About 1 oz. of the former at breakfast, and 2 pints of milk during the twenty-four hours together furnish at the most 2·6 ozs. of fat, allowing from ½ oz. to 1 oz. for that contained in the lean meat with gravies, &c. 3 to 3½ ozs. are obtained. It is doubtful if this is sufficient with exercise and low temperature, nor is it to be recommended that those with poor appetites should drink more milk. Persons should eat plentifully of butter at breakfast, especially as that meal is not a substantial one.

It would also be very advantageous to continue taking cod-liver oil if it had been found to agree in England, for reasons that are plainly apparent. Should the stomach have been unable to digest it hitherto, trial should again be made in a cold climate, as it might be then more easily assimilated, its oxidation being assisted by the increased proportion of nitrogenous material ingested. A good time for taking it is immediately after lunch or dinner in a glass of marsala, or in milk half an hour after a meal, commencing with one tea-spoonful, and gradually increasing the dose.

Pancreatine and pancreatic emulsion are sometimes valuable in assisting the digestion, and malt extracts also. All these substances can be looked upon as supplementary to diet, and not as medicines. If cod-liver oil is objectionable, butter should be eaten at every meal, or cream be made use of.

To further demonstrate the virtue in cod liver oil, fat, and butter, the following table taken from Frankland will give a clear idea of their force-producing value:—

(*a*) "The North West Passage By Land." Viscount Milton and Dr. Cheadle.

(*b*) It is questionable, if with the low temperature in the Alps, phthisical persons should be physiologically compelled to maintain much of the body-heat by the carbo-hydrates, as the changes in their principles previous to their becoming calorifacient take place in the liver; and the function of that organ is often impaired in phthisis.

In the event of high temperature supervening, the digestion of meats is greatly interfered with, and the usual diet stands in need of modification, as the nitrogenous matter will, if excessive, embarrass the digestive powers, and prove an encumbrance to the stomach, leading to further complications, which may be avoided by substituting food of a different nature that has not to undergo such a complicated process of absorption and elimination. For this purpose, milk and raw eggs are to be chiefly relied on, with beef-tea, soups, jellies, light puddings, toast, biscuits, and farinaceous substances, as arrowroot, or one of the numerous "foods." By this regimen, bearing in mind that the system requires much less nourishment when the body is at rest, an ample dietary is furnished. During bad weather, also, when but little exercise can be undertaken, and confinement indoors is called for, diminished diet proves of some service, not only to the comfort of the patient, but to his general condition, and, consequently, the local state of disease.

On the cold, dry days, with outdoor exercise, the appetite can be wholly satisfied, with safety and advantage, for it is on these occasions that the "push" is given to nutrition, and any excess in nourishment is more likely to be burnt up or assimilated in the system, to maintain heat, produce force, or counterbalance waste and change.

As the breakfast is not a substantial meal, it will be perceived that the latter part of the day, between noon and 8 p.m., is the period principally occupied by the digestive process, the remaining sixteen hours, therefore, will, in the case of delicate persons, prove to be a great tax on the force and heat-producing powers unless sustained in some way or other. Although it is impossible to lay down rules to apply to every one, a short dietary table for an ordinary case of loss of flesh can be modified to suit the temperament or capacity of any individual, bearing in mind that in many instances "suitable diet" is a matter of experiment.

Regimen at the Swiss Health Resorts.

7 or 7.30 a.m.—Warm milk, ½ litre.

8 or 8.30 a.m.—Breakfast: Tea, coffee, or chocolate, ½ litre; bread, butter, honey. Extras not provided *en pension*. Eggs, cold meat, bacon, omelette, &c.

Noon or 1 p.m.—Lunch: Soup, meats, sweets, cheese, 2 glasses of red wine, or wine and water (½ pint).

4 or 4.30 p.m.—Warm milk, ½ pint, with a biscuit, or other light refreshment, as tea, coffee, with bread and butter.

5.30 or 6 p.m.—Dinner: Soup, fish, or *entrées*, meats, sweets, cheese, red wine or wine and water (½ litre).

9 p.m.—Supper not provided *en pension*. Milk, ½ pint, with biscuit, &c., or beef-tea, or some "food" prepared with milk.

A glass of milk, with a biscuit, may also be taken sometimes at 11 a.m. if it is found to agree.

If night-sweats occur, nourishment should be taken at frequent intervals, especially during the night. Stimulants are efficacious at these times—whisky, rum, or cognac; but spirits should always be mixed with milk or egg, or both combined. Their efficiency seems to be increased in this way. Neat spirits as a "*petit verre*" cannot be recommended with much benefit unless there is food in the stomach. Brand's extract of meat, and Liebig's, are suitable also. These can be mixed together, when they form a better and more natural beef-tea than when taken separately. The Veltliner wine drunk with meals will act as a good astringent. A frequent cause of perspiration at night is an excessive quantity of clothes on the bed. The usual eiderdown quilt should not cover the patient if night-sweats are frequent. A flannel night-shirt is of great service on these occasions, and the temperature of the bedroom ought never to rise over fifty degrees. Fifty to fifty-five degrees is generally found to be a comfortable temperature in winter.

CHAPTER VII.

Exercise, Meals, Sleep, &c.

It is unnecessary to point out the need for individual management in this matter. Much will depend on the state of health and capability for exertion. One rule can, however, be laid down—viz., keep in the open air as much as possible. This will of itself entail a fair amount of movement, but if the state of the lungs do not preclude skating, tobogganing, or walking ascents—care must, of course, be taken in beginning exercise gradually. A state of breathlessness or fatigue must never be permitted, nor must the body be allowed to cool rapidly if perspiring.

The time available at these altitudes in the depth of winter is somewhat limited for delicate persons, as the sun at this time of the year remains but a short time in the valleys (five to six hours). It is therefore incumbent on those seeking health to make the most of this time, and when in-doors to breathe as much fresh air as can be admitted with comfort. Bedroom windows can be left a little open if the nights are clear, and the heat of the stoves regulated accordingly. In giving an outline of personal hygienic management a description of how the day may be passed will be of some assistance.

At 6.30 or 7 a.m. the stove should be lighted, and a half-litre of milk, warm from the cow, be brought to the bedside of the patient. After drinking this, an hour's sleep may be had. If a cold bath be prohibited, a rapid sponging of the chest and back, followed by friction, is of great service in keeping the skin in a healthy condition. A fairly vigorous patient may have a cold bath, or the chill may be taken off; but precaution must be observed in having the air of the bedroom at this time fresh and warm (not below 55 degs. F.), so that the deep inspirations caused by the shock of cold to the skin shall not take in the used-up bedroom air. A bath or sponging may be tolerated in many cases, provided it takes place *immediately on rising*, while the body is hot. If the skin be allowed to cool down by tardiness in preparing for the bath the water will feel intensely cold. Slight dumb-bell movements may be executed when dressed, throwing the shoulders back and taking deep inspirations. Soon after breakfast, which is taken at 8.30 or 9 a.m., the patient should get out for a walk, making a slight ascent if not too short of breath; and returning at 11 a.m. for a glass of warm milk. The afternoons are mostly spent in sitting out of doors, skating, coasting, walking, or sleighing—the latter is not to be recommended in very cold weather. Another half-pint of milk can be drunk in the afternoon, or a little light refreshment such as tea or coffee will do no harm, the patient being generally able to determine if it can be taken with benefit. If he finds it too much fluid, a less quantity of thin cream might be substituted. Symes Thompson gives a short piece of advice free from mysticism on the subject of exercise in the Alps (*a*) :—"Those in health need few restraints, but for those with active lung disease sudden exertion on arrival should be discouraged lest it lead to hæmorrhage. If there is active disease or hæmorrhagic tendency or moist sound in the lung, the patient should sit out in the sun till dry sounds replace moist ones. He may then walk on the level, or skate, or gently stroll up and down hill, thus causing deep inspiration. Quiet skating can be indulged in by almost all. 'Tobogganing' is more severe, as patients are apt to talk and laugh when walking up hill. This is very good for the vigorous, as it expands the chest. Lawn tennis is suited only for the strongest, in whom lung disease is quiescent."

The dinner hour varies in different hotels. At St. Moritz 7 p.m., Davos and Wiesen from 5 to 7 o'clock. Food should be taken leisurely, and masticated well. Half an hour's rest before and after meals facilitates digestion. The evenings are spent in various ways. Davos possesses a theatre and concert-room (*b*) and amateur theatricals are got up at the hotels, with concerts, tableaux vivants, &c. It would be a great boon if, on the occasions of such gatherings, artificial means were provided for the purification of contaminated air. With the intense external cold, air cannot be plentifully admitted to dilute the effete products of respiration, &c., therefore, although entertainments in crowded rooms generally conduce to a healthy frame of mind, and tend to banish despondency, evils may originate if sanitary precautions are neglected.

With respect to the length of time for sleep, the temperament and habits of the individual will have to be considered. The old dictum of 6 hours for a man, and 7 hours for a woman will scarcely commend itself to most people, nor does experience teach us that any definite duration of time for mental and physical rest can be determined with exactitude. The intensity of muscular, mental, or nervous exhaustion during the day will in all cases influence the desire for repose. Cold also predisposes to sleep, as may be witnessed in hybernating animals. Some human beings also hybernate. It will not be too much to say that 8 or 9 hours slumber in winter, at these cold stations, is near the mark; remembering that nothing is to be gained by remaining in bed in a semi-state of wakefulness after this time is past.

If smoking cannot be entirely given up, the quantity of tobacco used should be cut down as low as possible. Cigarette smoking should certainly be discontinued by those whose lungs are affected, as the habit generally acquired of inhaling the smoke or passing it through the nasal passages, proves very irritating to the mucous membrane, and is more injurious to the throat and lungs than the same portion of tobacco smoked in a pipe.

(*To be continued.*)

MELANOTIC ROUND AND FUSIFORM CELL SARCOMA OF ANTRUM—EXCISION OF SUPERIOR MAXILLA—RECOVERY. (*a*)

By ARTHUR TREHERN NORTON.

The patient came under my care for polypus of the nose, which he said he had recognised only three weeks. It presented itself to him as polyps of the nose usually do—a slight obstruction to respiration on one side of the nose, gradually increasing, or rather rapidly increasing in his case, for, as I have said, he had only discovered it three weeks before entering hospital. When he came to the hospital I found a black mass plainly visible on looking into right nostril, and on passing my finger behind the soft palate could feel the posterior extremity of the growth, not projecting into pharynx, but terminating in the nose a short distance from the posterior nares. On withdrawing my finger it was stained with blood, and patient then said that he frequently spat blood from the back of the throat. On examining it with the probe I found it unattached on the inner side, and I could limit it above, but on the outside part of the inferior turbinated bone was absorbed, and it was attached by a broad base in the region of that bone and above it: the right ala nasi was very prominent, from the pressure of the tumour within. I concluded from the position of the tumour, and knowing the nature of such growths, that it had arisen in the antrum, and grown inwards into the nose. I had no hesitation in stating it to be melanotic sarcoma, but, as one of the staff suggested, there might be effusion of blood in an ordinary fibro-myxomatous polyp, I caught a small particle in an artery forceps and excised it with curved scissors. Under the microscope it presented cells, some round and a few fusiform, all pigmented: there was no loose pigment such as would have been seen from the effusion of blood, but all the pigment was in the cells. I decided upon the immediate removal of the growth with all its attachments; and as it was not yet certain whether or not it had arisen in the antrum or only in the outer wall of the nose, I determined to investigate this point during the operation, and to be directed in the operation accordingly.

Operation.—I made the incision from the inner angle of the eye downwards along the side of the nose, then turned inwards below the ala and down the central line of the upper lip; with the scissors I next cut through the mucous membrane so to join lip and cheek to the upper jaw, and, using a lever instead of a knife, separated all soft tissues from the upper maxilla as far outwards as the malar bone; so that up to this stage of the operation there was absolutely no bleeding except from the first incision, which had been arrested by ligaturing the angular branch of the facial artery, and by the aid of cotton-wool I now ascertained that the antrum was full of the growth, so that nothing short of complete removal of maxilla would have been of any use. With the bone forceps I then severed the nasal process of the superior maxilla, together with the chief portion of the inner wall of the orbit; then, with one blade of the forceps in the orbit and the other beneath the zygomatic process of malar bone, the bone was separated from the outer wall of the orbit; next, an incisor tooth was drawn, and the hard palate cut through immediately along the side of the septum nasi, the bone being now separated with the exception of the palatine attachment to the pterygoid process. The mass was seized with the lion forceps and twisted from this attachment and drawn forwards and outwards, in order to separate with the scissors all the soft tissue attachments at the back of the mouth and palate, and thus completely freed. The skin was carefully re-adapted in the line of incision and attached by small sutures and united in such a manner that it is quite impossible to see where the incision was in its chief part. A subcutaneous injection of morphia

---

(*a*) Read at the British Medical Association, Liverpool.

was administered, and the diet was milk, small pieces of ice, &c.

The temperature never rose above 99 deg., nor the pulse above 80. The wound was continually syringed with a solution of Condy's fluid, and as the wound was naturally drained of all secretion, none could be retained and none absorbed; hence the complete absence of all symptomatic fever or constitutional symptoms. On the Wednesday following, that is, one week from the date of the operation, the patient was walking about the ward, and in twelve days after the operation he left the hospital.

INFANT MORTALITY. (a)

By T. M. DOLAN, L.R.C.P., F.R.C.S.Ed.,

Medical Officer to the Halifax Union Infirmary.

In discussing the question of Infant Mortality in its relation to the employment of women in factories there are a few general principles influencing infant mortality which should be kept in view.

It will be almost generally admitted that during the first months of infant life warm and breast milk are two of the great requisites for the sustentation and development of the tender little human organism, and that when the infant, through any cause, is deprived of those two great requisites, it must suffer, unless it is provided artificially with substitutes.

The woman, factory operative, or fashionable mother, who fails to supply either the natural requisites above indicated, or artificial substitutes, must add to the infant mortality of the country. If we admit these principles, we shall, I consider, be in a better position to discuss the subject.

One great argument used by those who are opposed to any legislative or philanthropic interference through the agency of individual manufacturers, with the employment of women in factories, is derived from a comparison of the statistics of different towns. Thus, one writer (b) who has paid considerable attention to the subject, and whose words are consequently entitled to consideration, furnishes us with a table of the deaths of children under one year of age in a certain number of towns; and as the death-rate in such towns as Liverpool and Sunderland, where there are few manufactures, is high, he assumes that the theory of a high death-rate of infants, owing to the employment of women in factories, is disposed of by this fact.

But may there not be certain factors in existence in Sunderland and Liverpool which are not to such an extent in existence in manufacturing towns to account for this high death-rate, or may not the very same causes be in operation there—viz., neglect of infants during the first days of infant life, owing to dissipation, carelessness, poverty, intemperance, ignorance, &c.

The statistical method is not always the best for the elucidation of truth. Fonssagrives (c) says:—

"La statistique bien faite est bonne, la statistique mal faite est mauvaise; c'est un levier qui soulève la pierre sous laquelle est la verité, ou qui, la laissant retomber, l'emprisonne plus étroitement." ("The statistical method, according to its application, may be good or bad. It is a lever which may raise the stone under which truth lies, or may imprison it more closely by mal-application.")

It is the interpretation put upon *figures* which vivifies them. Unfortunately, the interpretation is too frequently coloured by individual prejudices. Some economists look upon figures alone as the sole means of testing the accuracy of any question. Economists of this class say, "Produce figures that will show that the death-rate of infants under one year of age in manufacturing towns is greater than that of towns where there are no manufactures. Without such figures you fail to prove your case, and your reports of special commissioners, factory inspectors, medical officers of health, are worthless."

We can produce statistics which prove that the death-rate of infants, the offspring of women who are engaged as operatives, is so high as to require some special explanation to account for it; and still more, we can furnish evidence which seems to connect this high death-rate with the employment of women in factories.

Though the death-rate in non-manufacturing towns may be equally high, we can also give a reason for this, by a consideration of the factors which are always concerned in the production of infant mortality. The sole evidence of figures is not sufficient; we must interpret the figures.

The question will at once suggest itself, what evidence can we bring to support the theory that the employment of child-bearing women, before and too soon after confinement, favours infant mortality?

We must fall back upon the general principles I have previously alluded to in reference to the requirements of infant life during the first days of existence; and if we can show that the conditions of operative life, and the customs which are connected with it, lead to not a wilful, but a routine neglect of infants during a period critical in the extreme to the well-being of the infants —if we can prove from observation and medical experience that infantile diseases follow as the result of the deprivation of the natural food of infants, we may fairly claim to have substantiated our position.

If, after the birth of a child, through any exigencies, a woman resumes work within fourteen days of her confinement, and leaves her child to the care of a hireling, thus depriving the child of that food which was intended by Nature for its sustenance, does she not potentially contribute to some of the causes admitted by all as predisposing to infantile disease and death?

My answer must be in the affirmative.

Have we any evidence to prove that mothers of the factory operative class resume work at an early date, or that their children suffer in consequence of this custom?

In 1872 I published a small pamphlet on "Infant Mortality," in its relation to the employment of women in factories. The facts which induced me to write this paper may be thus briefly stated:—

Up to that date I had attended 768 confinements, chiefly amongst factory operatives. I observed that the mothers rested but a very short time after confinement, and I calculated that the majority resumed work within a fortnight.

Independently of the personal danger to the woman from resumption of work at such an early date, I had practical experience of its results on the children. I saw infants thriving during the first fortnight. I saw the same infants at the end of a month or six weeks. During the time they were receiving a mother's personal care they thrived; when deprived of this they pined. The mother who went to work left the child in the care of some old woman, or if she had children over seven, in the charge of one of them. The infant received breast-milk during the night, in the morning, and at meal times, at other times receiving food by the bottle. I need not attempt to paint a fancy picture of the tired mother, only a fortnight confined, nursing her child during the night and in the hurried intervals of meal-time, or point out how unfit she must be, however willing, under such circumstances, to nurse her child.

Without doubt the general ignorance prevailing on the principles of infant feeding intensify the evils arising from the separation of a mother from her infant, but this does not in any way lessen the culpability of the practice. It is a reproach to our civilisation that such ignorance should prevail, and it is no excuse to say that it is in consequence of this ignorance, and not on account of the employment of women in factories that the high death-rate of infants in large centres of population is due.

(a) Read before the Social Science Congress.

(b) Whately Cooke Taylor, *Fortnightly, Contemporary Review.*

(c) "Hygiene."

I also observed that infants confined in the workhouse at the end of a month were stronger and healthier than those of the operative class. Mothers who were admitted into the maternity at the workhouse had a full month's rest after their confinement, during which time they were able to give their infants their personal care. Thus the recipient of Poor-law relief was in a better position than her hard-working sister.

I was farther able to test the relative mortality of infants in the workhouse and infants of the general factory population, and I found that whilst taking into account the number of births, the infant mortality of the workhouse was proportionately lower.

Believing, then, that the infant mortality of the district was to some extent favoured by the employment of women, I consulted the register of deaths of the town, in order to ascertain the mortality, and found that the total number of deaths for the year 1872 was 1,770, out of which number 447 were infants under twelve months, and 261 over twelve months, but under five years, so that out of a total number of deaths of 1,770, we have 708 of children under five years of age. To whatever cause this may be attributable, such a proportion of deaths in children under five years was appalling, and called for a remedy.

Another observation made by me was that many mothers worked in the mill up to the very day of their confinement. As a consequence of this practice, I attributed for various medical reasons the bringing forth of stillborn children, though there is another factor to be allowed for in connection with stillborn infants, viz., the employment of midwives unacquainted with the methods of restoring asphyxiated infants.

For the sake of argument I shall take a very low estimate of the number of children whose premature death I assigned to the deprivation of a mother's care during the early days of infancy, and up to the year 1872 I fix it at the low rate of 15 per year.

As there are nearly thirty practitioners in the town, I fairly presumed that their experience would be somewhat similar to mine; in fact, every medical practitioner I have spoken to on the subject agreed with me in my general deductions, and said that their experience furnished them with frequent illustrations of the evil results arising from the practice in question.

I pushed my inquiries further, and asked several practitioners whom I knew, and who attended a large number of operatives, "Could you fix the annual number of infantile deaths during the last five years attributable in your opinion, to the employment of the mothers in factories before or too soon after labour."

Five replied fixing the mortality at 15 to 20 per annum, two were of opinion that 20 per cent. of infantile deaths should be assigned to this cause.

My own personal convictions were thus strengthened by the testimony of other observers, so that I considered myself justified in drawing the attention of the public to this factor in the production of infantile mortality.

Since 1872 I have had more extended experience among the operative class, having attended over 2,000 cases of midwifery amongst that class. My increased experience convinces me of the correctness of the views I took in 1872.

It is singular how unanimous nearly all medical officers of health are in assigning the employment of women in factories as a cause of infant mortality. Thus, from many instances, Dr. Harris Butterfield, medical officer of health for Bradford, in his report on the health of that town for the last quarter of the year 1874 (*Lancet*, vol. i., p. 423, 1874) comments on the excessive mortality of infants in our large towns. This mortality he attributes in a great measure to the too early weaning of infants by mothers employed in factories, and to the ignorance of mothers on the subject of feeding and clothing.

Dr. Dudley, medical officer of health, Staleybridge (*Lancet*, vol. i., 1874, p. 849), in his report, also calls the attention of the sanitary authorities to the excessive infant mortality of the district. This he attributes to the same causes.

I feel some satisfaction that the same subject has been deemed worthy of discussion in the Health Section of the Social Science Congress.

One good result will, I trust, follow. We shall have some light thrown upon the causes of our high infantile mortality, and still more, whether the factors be ignorance, carelessness, bad and improper feeding, "Godfrey's" cordial, intemperance, improvidence, illegitimacy, or the employment of women in factories, we shall have a remedy suggested. We cannot now be satisfied by such explanations as the dispensation of Providence or the survival of the fittest; but in view of what has been done in our large maternities, workhouses, and hospitals, we must endeavour to diminish the infantile mortality, which, from whatever cause, is a disgrace to our civilisation.

During the ten years 1870 to 1879 the rate of infant mortality in twenty of the largest English towns, measured by the proportion of deaths under one year, to births registered, averaged 171 per thousand. The lowest rate was 141 in Portsmouth, London and Brighton coming next, with 158; the rates ranged upwards in other towns to 187 in Bradford, 188 in Manchester, 197 in Leeds, 216 in Liverpool and Leicester.

When we remember that a rate of 103 to 110 per 1,000 represents the death-rate of healthy districts, we can form an idea from the preceding statistics of how much infantile life is annually wasted in our large centres of population.

In view of my data and conviction that the employment of women in factories conduces to infant mortality by taking away the mother from her infant at a period when the natural sustenance, breast-milk, is of the greatest value, what remedy do I propose?

Those who are familiar with the literature of the subject will be aware that several schemes have been put forward.

The Legislature has been asked to interfere. The mother should be required to absent herself for six weeks, three months, six months, &c.

One writer, the late Professor Jevons—whose premature death we all must deplore as almost a national loss—went so far as to formulate that the child-bearing woman or mother should not be employed in factories until her children were three years of age. It is a matter of regret he was not spared to attend this Congress to explain and defend the propositions set forth in the January number of the *Contemporary Review*, and to reply to Mr. Whately Cooke Taylor's article in the September number.

The economical aspects of this question are very important, and cannot be overlooked. The child-bearing factory operative by her wages contributes very materially to the family income, and thereby to the well-being of the family. Any interference with the wage-earning power of this class would in many cases inflict a hardship. It is true that in view of the general happiness and good of the community individual interests must be sacrificed.

May it not be possible, without any excess of individual sacrifice, and without any legislative interference, to bring about a reduction of infant mortality? I think so. We have a precedent to guide us.

M. Jean Dolphus, one of the largest manufacturers in Alsatia, found that the women employed in his factory lost 40 per cent of their children in the first year, the average mortality at that age being there 18. He concluded that the main cause of loss was the necessity of the mothers to resume work too soon after their confinement, thus neglecting their offspring, and with the true grandeur of a merchant prince determined to pay every woman in his service, who was confined, six weeks' wages without requiring any work for it. The result was that after three years the infant mortality decreased from 40 to 25 per cent. Six other manufacturers have followed his example, but with a modification. They have not given six weeks' wages, but recommend their *employées* to make themselves participants by a subscription of three sous a fortnight, from all women in their factories between the ages of 18 and 45. The premium is not sufficient to cover the risk, but the firms have themselves contributed the balance.

The experiment of M. Dolphus and the modifications introduced by his imitators indicate the lines on which I should like to see reform proceed. It should not be difficult to secure the aid of employer and *employé*. As a tentative measure its adoption would enable us to feel our way. In this case we would be wise in adopting the motto, "Festina lente." I would advocate, then, a system under which each woman should absent herself for six weeks, a fortnight before and one month after confinement. The fourteen days will enable the woman to attend to her personal hygiene, and to leisurely prepare for an event which is always fraught with danger. The month's rest will benefit the mother and put the child in a fair way towards a subsequent healthy development.

I am well aware that many objections will be raised against such a scheme. What better will the infant be when the mother resumes work and the infant is handed over once more to the care of the ignorant old woman with her "Godfrey's" cordial and her improper system of feeding?

There are supplementary agencies which we must employ to correct the prevailing ignorance in reference to infant feeding, and no scheme of reform will be perfect which does not take into account the other factors which are concerned in the production of infant mortality.

We must endeavour to diffuse amongst the masses a knowledge of the general principles of infant diet and nursing; we must instruct the potential mothers, the young girls who will be the future mothers of the country. This we can do in many ways—by popular lectures, like those given by the St. John Ambulance and other kindred associations, and we can utilise our Board schools for the purpose.

Young girls nurse their little brothers and sisters at a very early age; we must teach them how to nurse rationally. Thus we shall get rid of the evils of the foul fungus-bearing bottle.

At the birth of each child each householder is supplied by the registrar of the district with a vaccination paper. I would suggest that a short code of rules on infant feeding and nursing should be drawn up by some competent authority and printed on the vaccination paper; thus we shall secure a free and general distribution of these rules. Crèches should also be established. Without these supplementary agencies all schemes—such as six weeks', three months', six months' abstention from work will be imperfect.

Another objection will be raised as to the method of registering the fact of a woman's pregnancy—the date of her confinement, so that we may provide for a six weeks' absence from labour.

If the mother will not lose any wage by her absence, there need not be any difficulty on this point.

The question we shall next consider is, how shall we provide for the payment of the woman during the time she is absent from work?

The plan devised by M. Dolphus was a very noble and generous one. Manufacturers in this country would be quite capable of raising to a similar level if required.

Is such a course expedient?

In my opinion there should not be any eleemosynary elements in this scheme, unless in exceptional cases. I therefore prefer the plan adopted by the manufacturers who followed the initiative of M. Dolphus.

It should not be difficult to devise a plan or system by means of which the operatives might contribute to a fund from which they could draw at the time of their confinement.

At Mulhouse such a fund already exists; so that on the Continent the employment of women in factories has been recognised as a cause of infant mortality, and measures taken to prevent it.

It would be no hardship to expect the operatives to contribute to a fund from which they would derive so much personal advantage. The steady, industrious operative can well afford to put something by for the benefit of his wife.

For the completion of a scheme of this kind we shall have to obtain the sympathy of employer and *employé*.

If we should fail in securing a loyal and intelligent co-operation—if we found after a short trial that this plan did not act, then I would say we must have compulsory legislation with pains and penalties to enforce the prohibitory regulations.

I may illustrate another and frequent cause of infant mortality by the following case:—

On Aug. 15 I attended Mrs. D. I went to her at half-past 6. She was confined at half-past 8. She had worked all day at one of the largest and best mills in Halifax, and worked although she had pain. The child, when born, was asphyxiated. It took over ten minutes to restore animation. Had an ordinary midwife been in attendance a stillborn child would have been registered.

Here I may observe that the employment of midwives is very common, and may lead to an increase in our infantile death-rate. A good midwife may be, and is, a boon; an ignorant midwife is a danger to society.

In the present aspect of the question one great step towards reform might be secured by the appointment of a committee of this Congress. This committee might collect statistics — as, for instance, the number of women employed in factories, their average earnings, &c. They might sound employers and employed, and ascertain their opinions on proposed measures of reform.

There is one agency which should be enlisted in this social question—the agency of women of education. Here is a field for the great suppressed energy of our sisters, an energy which is now seeking to develop itself and to find vent in other directions. Ladies should interest themselves in the cause of the hard-working, industrious, factory female operative. This is the character I give them from my personal experience. The stern laws of fashion bind the female operative in customs which are detrimental to her own and infant's health.

The female operative is affectionate, and loves her child according to the light which is in her. It is a large question as to whose fault it is that her light is not a bright one.

In conclusion, I have no doubt that, though we may differ on the causes of infantile mortality, we shall agree, however, that an infantile death-rate of *two hundred and sixteen* per thousand in Leicester and Liverpool imperatively demands remedial measures. Here is a waste of human life which should be, at some time, of some value to the country. The shibboleth that population increases faster than the means of subsistence is disposed of by our power of increasing by scientific means our food supply.

The Social Science Association has done much in the past to promote the general health, happiness, and well-being of the country by the discussion of those great social problems affecting modern life. How much it has achieved may be seen by consulting the little work published by the energetic secretary, Mr. Clifford Smith. It will gain an additional title to support if it should be the means of throwing light on the causes of our high infantile mortality, and still more, if it should lead to the adoption of remedial measures, it will merit the thanks of succeeding generations.

Clinical Records.

DELIVERY PREVENTED BY AN ENLARGED SPLEEN IN THE CHILD.

Under the care of Mr. J. WEBBER, of Dinagepore, India.

[We are indebted to Surgeon-General Chas. R. Francis for the Report.]

A well-formed native female, æt. 20, was delivered of her first child, under the care of the Civil Surgeon of Dinagepore (India). Throughout the entire period of gestation she had suffered a good deal from malarious fever, the attacks recurring three or four times in each month until the seventh, when severe hæmorrhage came on. This prostrated her very much, and she remained weak until delivery at the usual period. Dinagepore is considered, amongst the servants of Government, as one of the three penal settlements of Bengal, owing to their malarious climate, Rungpore and Purneah being the other two. Considerable difficulty was experienced in the delivery. The patient had been in labour several hours when the Civil Surgeon saw her. The head was then protruding much beyond the external outlet. The labour pains had ceased, and the child was evidently dead. The face was livid and partly decomposed. The Civil Surgeon rectified the position with facility, brought the shoulders round, and hooked down the arms with his fingers. Steady traction was then made for two or more hours without any advance. At this time the head became detached. The woman was then placed under chloroform, and podalic version was performed. Still no delivery. On examination the abdomen was found to be distended with, apparently, an enormous and hard tumour. It was decided to, if possible, break it up. This was done. Two fingers of the left hand were introduced, and a guarded scalpel, held in the right, was passed in, and made to perforate the child's abdomen. The finger completed the operation of breaking the tumour up into several pieces, which were extracted separately, and with some little difficulty. When this obstruction was removed, the further delivery was readily accomplished. In eight hours the placenta came away. There was no flooding, and the patient made a complete, though slow, recovery. *The tumour was an enormously enlarged spleen.*

France.

[FROM OUR SPECIAL CORRESPONDENT.]

Cholera.—The recent circular which the English Government has sent abroad on the charge brought against it in reference to the epidemic of cholera was published *in extenso* in the *Gazette des Hôpitaux*, and followed by reflections, which plainly indicate that the explanations furnished by Lord Granville were in no wise sufficient to convince the editor of the *Lancette Francaise*. It is quite amusing to read the charges brought against the Minister as to his motives in publishing the circular, but the most ludicrous one, and that which excites the choler of the journal is, that throughout the whole length of the letter the Government seemed to ignore, or in any case took no notice of the accusations brought against it by M. Fauvel a few days ago, before the Académie de Médecine. It reproaches Lord Granville with only having read political journals, an unfortunate circumstance it is true, which might have been avoided if a copy of the *Gazette des Hôpitaux* had been forwarded to him. However, the journal consoles itself with the fact that the official letter appeared a week *posterior* to the remarkable feat of M. Fauvel, and consequently it is not impossible that our *confrére* may have exercised some influence on the British Government. In any case the precautions taken by England to stamp out the epidemic has shown their fruit, and in a few days we will speak of the cholera as the *recent* epidemic. However, there are certain parties in France who would experience a sort of inward satisfaction if the half of London were attacked to-morrow with the disease.

Strangulated Congenital Hernia.—At the Société de Chirurgié M. Trélat communicated a case of congenital strangulated hernia operated on, and the patient died the following day from congestion of the lungs. It was the case of a man aged thirty, who was admitted into the hospital for strangulated hernia. Taxis, baths, and every other means were tried in vain, and M. Trélat determined to operate, although the symptoms were not of a nature to make the operation imperative. The result was as had been indicated. M. Berges remarked on the case, and said that pulmonary complications were very frequent in this accident, he considered that renewed attempts at taxis were dangerous, and in his opinion if, after the first trial, no success followed, the operation should be made without delay. M. Chámponniére was of the same opinion, and he attributed the fatal issue to the repeated attempts at reduction. M. Desprès followed in the same line. The patient should be placed in a bath for an hour, and if the taxis did not then succeed the operation is necessary at once.

M. de St. Germain, of the Hôpital des Enfants Malades, treats erectile tumours by the liquor Piazza, of which the following is the conposition :—Perchloride of iron ʒj., chloride of sodium 45 grs., water ʒiij. A few drops are injected into the middle of the tumour with a Pravaz syringe, coagulation of the blood soon follows. No after dressing is necessary. M. St. Germain is not favourable to the vaccination of the tumour, as it often leaves an ugly cicatrix, the thermo-cautery neither is not preferred, as if it is at a bright red it is likely to cause hæmorrhage, and of a sombre hue it only burns the skin. Vienna paste is also objectionable, as when employed on thin skin it is liable to cause hæmorrhage.

WOOD-WOOL, A NEW SURGICAL DRESSING.

Notwithstanding the great success that attends wound treatment in modern times, thanks to Listerism, it has still been felt that there was room for improvement. Although it may not be possible to improve much on Listerian dressings in the matter of results, all are agreed that if we can get as good results with a simpler and cheaper form of dressing, a great step in advance will have been made. As we heard remarked the other day by a busy surgeon "although I adopt the Listerian treatment when possible, I have to do an enormous amount of surgical work in the alleys and back streets of the town, and if I practised strict Listerism I could not possibly do the half I am called upon to do." What has been wanted is a dressing that can be applied in as short a time as any other, but which will at the same time assure, as much as is possible, an aseptic course of repair in the wound.

In Germany, at any rate, the reign of carbolic acid is over, and corrosive sublimate, or sublimate as it is there called, reigns in its stead. Many substances impregnated with sublimate, such as glass-wool, ashes, sand, &c., have been employed as attempts at permanent dressings with greater or less success. Something has still been wanting, something that will absorb a large quantity of discharges, and at the same time remain aseptic.

With efforts directed towards the discovery of such a material Professor Bruns, of Tübingen, has hit upon something to which he has given the name of wood-wool (Holzwolla). It is finely ground wood, such as is extensively used in the manufacture of paper. It is a clean looking, delicate fibred, soft, yellowish-white substance, having an odour of fresh wood, and it has the characteristic of being able to absorb an immense quantity of liquid.

The best wood-wool, *i.e.*, that possessing the highest absorbent properties, was found to be that which was obtained from the *Pinus picea*. The wood-wool thus procured was first pressed, passed through a sieve, then dried and impregnated with a solution containing half per cent. of sublimate and 10 per cent of glycerine. The processes were first carried out under the personal supervision of Dr. Bruns, but it was soon found desirable to put the preparation of the dressing into the hands of a regular manufacturer. It was accordingly put into the hands of P. Hartmann, of Heidenheim (Würtemberg), whose preparation gave every satisfaction. The wood-wool, impregnated with 5 per cent. of glycerine or not, may be now procured from him.

The advantages claimed for this dressing are numerous. It is cleanly, fresh, and of a whitish colour, it is at the same time soft and delicate in texture as cotton, and "extraordinarily cheap." The actual price is, however, not stated. It possesses some antiseptic properties naturally, has an agreeable odour, and is exceedingly elastic even in thin layers, so that bandages can be put on more lightly with this than with any other dressing. Its absorbent properties are so high that it takes up twelve times its own weight of water, so that ten grms. of well dried wood-wool after complete saturation attain a weight of 130 grms.

Dr. Bruns claims that high absorbent qualities in surgical dressings are of vast importance, "as primary wound healing takes place the more readily, the more completely the discharges are conducted from the wound—the drier the wound and its vicinity are kept—as it is under these circumstances that decomposition processes are most securely excluded. If the dressing has absorbed the secretions of the first few days, the evaporation and drying up of the contained moisture should be permitted; then, as the discharge from the wound diminishes, the dressing, now dry, can remain a considerable time as a permanent one. With this object in view, it is indispensable to omit the occlusive layer of the typical Listerian dressing, as the drying of the dressing is prevented by it. With the same object in view I prefer the covering of the wound with glass-wool, in place of the protective, as under this the suture line is of necessity kept moist."

In his own clinic the mode of dressing is exceedingly simple. After the wound has been disinfected by copious irrigation with a 1 per cent. (·1 per cent. ?) solution of sublimate, and the drainage tubes have been placed in, the suture line is covered with a layer of glass-wool. Upon this is placed a sufficient quantity of wood-wool either simply wrapped in sublimate gauze or sewn up in the form of a pillow. The latter form is preferred for hospital use. He considers it best then first to place on the wound a small pillow, then a larger one that will widely overlap this in all directions. These are to be fastened on by a firm binder. He summarises the results obtained by him with this dressing between the dates November 1st, 1882, to March 15th, 1883. 180 considerable operations and wounds were treated with sublimate antisepsis, the majority with wood-wool. In the case of those treated with wood-wool the first dressing with few exceptions remained from one to four weeks untouched. Occasionally patches of moisture were visible on the dressing on the earlier days, but within a short time these became dry and remained so, and when the dressings were changed the wounds without exception were absolutely dry and free from irritation. With the exception of one case of erysipelas no complication was observed throughout.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 29, 1883.

THE MEDICAL BILL.

We announced last week—by anticipation—the withdrawal of the Medical Bill for the present session. We formed this forecast upon the unbending and impracticable attitude assumed by Mr. Mundella, being fully aware that the second reading of the Bill was doubly blocked by the Irish and Scotch Corporations, and that Mr. Mundella was unwilling even to consider the propriety of making to these bodies the concessions which alone would induce them to withdraw the blocking notices and permit the Bill to be discussed after midnight on Wednesday. The only hope of passing the measure lay in the removal of these blocks, and the opposing bodies declined to remove them until their views were met. Mr. Mundella, on the other hand, would not negotiate until the Bill had passed the second reading; but, as he must have known that the opposing bodies would have given the Government complete command of the situation if they permitted that stage to pass, he could not reasonably have expected them to yield without receiving definite pledges as to the needful concessions.

As we reported last week, the three Scotch and two Irish Corporations had arrived at a league, defensive and offensive, to obtain eight amendments, which were as follows :—

1. That the Scotch Medical Board should consist of eight University to six corporate representatives, instead of eight to three, as provided by the Bill.

2. That the University and corporate representation on the Irish Board should be equalised by giving a third representative to the Irish College of Physicians.

3. That one-half of the delegates sent forward by these Medical Boards to the Medical Council should be chosen by the corporate representatives exclusively and the other half by the University representatives.

4. That the minimum curriculum of study, as well as the standard of examination for final examination, shall be equal in all divisions of the Kingdom.

5. That to obtain such equality the Medical Council, and not the Medical Boards as proposed, shall construct the scheme of education and examination.

6. That all members of the Medical Council (whether nominated by the Crown, delegated by the Medical Board, or elected by the profession at large) shall *ipso facto* have seats on the Medical Board for their own division of the Kingdom.

7. That the surplus funds of both the Medical Boards and the Medical Council shall be equitably distributed by the Medical Council to those licensing bodies which sustain pecuniary loss by the new system.

8. That the low examination fee reserved by the Bill for the benefit of University students shall be restricted to Arts graduates, or at least to *bona fide* undergraduates in Arts of 3 years' standing.

These were the demands submitted to Mr. Mundella, and we think they will be generally regarded as at least a reasonable basis for negotiation. There seems to be nothing in them inconsistent with the principle of the Bill, nor with the recommendations of the Royal Commission, nor with what is fair to the public and to all institutions concerned. They are directed, as our readers will observe, to the following objects :—*a*. To reduce in some degree the enormous domination in the medical education of the country which the Bill gives to the Universities at the expense of the Corporations. *b*. To ensure that one Medical Board shall not abstract students from another by accepting low-class education. *c*. To secure for the direct representative of the profession his legitimate influence in the settlement of medico-educational affairs. *d*. To provide for an equitable allocation of accumulating funds. These are all legitimate objects of agitation, and, anxious as we are for medical reform, we cannot blame those who pressed such points, and who refused to accept a Bill which does not contain them.

We believe that Mr. Mundella has been greatly misled by advisers who took too little count of the influence of those who desired amendments. He seems to have been led to believe that his Bill was perfect and needed no improvement of detail, and that it was his duty to pass it without regard to the views or interests of any of those parties concerned.

We trust that the demonstration of the Scotch and Irish Colleges will satisfy him that legislation in this way will be hardly possible, and certainly difficult and tedious. If this conclusion should lead him to bring the Bill of next year into conformity with the demands to which we have referred, we believe we may promise him for the measure an easy and rapid transit through Parliament.

LEAD-POISONING.

The conveniences and elegancies of modern civilised life are in too many instances obtained at a cost involving a considerable sacrifice of human life and comfort, being dependent on the development of manufacturing industries, the workers in which are necessarily exposed to dangers inseparably associated with their employment. It is, however, an evidence of hastening progress that the number of such dangerous occupations is being certainly, if not rapidly, reduced ; and we may confidently anticipate that the time is approaching when improved methods of production will effectually obviate the worst dangers with which we are familiar in this connection.

Such an Utopian period has, however, not yet dawned in regard to the white-lead industry, which affords employment to large numbers of men, and still larger numbers of women, in different parts of the United Kingdom, and which is annually chargeable with a perceptible proportion of the deaths which go to make up the yearly mortality of the country. The subject has been frequently dwelt on by official writers, and in the columns of the professional press ; and wishes have constantly been expressed to the effect that some means of averting the dangers in connection with this manufacture could be devised. The nature of the process whereby white lead is produced is such that those associated in making it are subjected to its toxic influences throughout their daily labours ; and, as is well known, innumerable suggestions have been made—and often enough adopted—with a view to minimising the evil consequences attending it. Thus, frequent washing, free ingestion of acidulated drinks, protective clothing, respirators, ventilation of an effective description, and other precautionary measures have been liberally resorted to, and it may fairly be said that employers of labour have shown commendable alacrity in carrying out one and all of these means of prevention as far as they have been able. They have, however, to deal with the least easily influenced classes of the population, for the majority of those who pursue the occupation of white lead making as a means of livelihood are either too careless or too callous to observe a systematic adherence to measures for preserving their own health. Consequently, the staff of every hospital situated near any centre of the industry is distressingly familiar with the symptoms presented by sufferers from this particular kind of poisoning ; and the mortality of such institutions is swelled by the additions it receives from this unfortunate class of patients.

In a pamphlet published by Messrs. Hamilton, Adams, and Co. this subject is discussed, and the attempts made to remove existing abuses are illustrated by quotations from official correspondence, &c. The object of the author, however, is twofold. In addition to showing the extent of injury produced by the present system of manufacture, he essays to find a remedy for it, and this he conceives to be in an improved process invented by Professor Gardner, and in use at Deptford. Anything in the nature of a substitute for the material itself has but little chance of being successfully introduced, attempts in this direction, however assiduously prosecuted, having been hitherto uniformly failures. It is a result of experience that nothing so admirably serves the requirements of a "body" for paints as white-lead, or combines at once the characteristics of durability, economy, and appearance so completely. Mr. Gardner's process provides for the preparation of lead carbonate in closed chambers, the agency by which the conversion is effected being electricity in the presence of carbonic acid generated by a special apparatus; and the whole time occupied in the conversion being very much reduced in comparison with that now in vogue. The principal feature of the new process, however, is the arrangement whereby all necessity for operative manipulation of the material is done away with, and all risk thus avoided of lead-poisoning by those engaged in the manufacture. If it should eventually stand the test of commercial competition, there can be no question that white-lead so produced will be preferred to that which can only be made at the expense of human suffering, and often enough of human life also.

◆

Notes on Current Topics.

The Sanitary Condition of Weston-super-Mare.

In a memorandum to the medical department of the Local Government Board, Dr. Blaxall communicates the results of his inquiry concerning the sanitary condition of Weston-super-Mare, this proceeding having been called for in consequence of two separate families contracting typhoid fever after staying at the same lodging house last autumn. After describing the circumstances under which the outbreak occurred, and tracing it mainly to inefficient drainage and tainted water supplied for drinking purposes, Dr. Blaxall remarks generally on the sanitary condition of the town in a way that should be carefully considered by all who incline to it as a health resort. "Upwards of 400 houses in the town are dependent upon wells for their drinking water. Now, considering that the town is traversed by drains and sewers, *more or less of an imperfect character*, and that the soil is polluted by soakage from surface nuisances, such wells must be regarded as affording a dangerous water supply. The extent to which these wells are exposed to pollution is manifest from the fact that out of 240 samples of water examined by the medical officer of health, upwards of 100 afforded evidence of contamination, and several of these on being submitted to analysis, were reported to be so highly polluted as to be unfit for drinking purposes." This is what may be called information of vital interest to intending visitors to Weston. But it is not the only hint afforded by the report, for Dr. Blaxall goes on to say of the lodging houses frequented by various classes of visitors, that having inspected several of each kind he is "satisfied as to the general prevalence in them of conditions that exercise an injurious effect upon health. This is especially the case with reference to the facilities offered for the direct escape of sewer-air into the dwellings" by lack of adequate arrangements to the contrary, and many instances of grossly unsanitary construction were noticed during the inspection. It is by no means to be wondered at that one of the recommendations with which Dr. Blaxall concludes his report, is to the effect that the lodging houses so conspicuously and harmfully constructed and arranged should be regulated under section 70 of the Public Health Act, of 1875. Meanwhile, tourists will do well to give Weston a wide berth.

Builders' Conscience.

The multiplied evils committed by those responsible for the wretched structures which do duty for "houses" in many districts where bricks and mortar, or their substitutes, are rapidly displacing the trees and shrubberies surrounding London, have recently been more than once brought prominently into public notice. In not a few instances official interference with the habits and customs of "jerry" builders has resulted in a wholesome reform of traditional proceedings, and in the replacement of fairly habitable dwellings for the unservicable tenements run up by speculative investors. In this connection, however, some interesting information was adduced at the Highgate Police Court lately, the ways of builders of "jerry" property having in this instance received full illustration. A summons had been granted against a builder who was charged with having employed a substance consisting mainly of garden mould instead of the necessary mortar destined to hold together the bricks composing the walls of the houses in question. With a leniency which deserved a better reward, this summons was adjourned in order that opportunity should be given for amending the imperfect work; but with an ingenuity which commands unwilling admiration the builder utilised the period of grace to complete the dwelling in accordance with his original designs—garden mould mortar, and all—and then lapsed into liquidation. It is not surprising that the district surveyor condemned the houses as worthless; and that the enterprising proprietor was re-summoned on account of them. At his second appearance before the magistrate he received that amount of justice to which his conscientious disregard of the order laid upon him previously entitled him, and was condemned to the payment of cumulative penalties amounting in the aggregate to £100; a result which might be most worthily imitated to the public advantage in numerous similar instances of inexcusable neglect. Whether payment of this fine or its alternative course, imprisonment, be resorted to by the builder, there can be no question that the incident will react as a healthy stimulus to other speculators of elastic conscience, to induce them to respect the health of those who may become tenants of the houses they erect, and thus directly result in the welfare of a large proporportion of suburban residents.

Sanitary Institute of Great Britain.

The 1883 Congress of the Sanitary Institute of Great Britain is fixed to commence on September 25th next, at St. Andrew's Hall, Glasgow, and will continue for five days. An exhibition in connection with the meeting will be inaugurated on the same date in the Burnbank Drill Hall, and will remain open till October 20th. Following the example of previous years, [the Congress will be divided into three sections, as follows:—1. Sanitary science and preventive medicine; under the Presidency of Professor Gairdner, M.D., LL.D. 2. Engineering and architecture: President, Prof. T. Roger Smith, F.R.I., B.A. 3. Chemistry, meteorology, and geology: President, Dr. R. Angus Smith, F.R.S. The duties of President of the meeting have been undertaken by Professor G. M. Humphry, of Cambridge, who will deliver an introductory Address on September 25th, at eight o'clock in the evening. There is every prospect that the Congress will be a most successful gathering.

Congenital Unilateral Atrophy.

The American *Medical News*, for August 11th, contains an interesting paper by Dr. S. Pixley, descriptive of a male child, now more than seven years old, and who exhibits the extremely rare deformity of complete unilateral atrophy. The right side of the head is much smaller than the left, and the superior and inferior maxillary bones of the right side are so diminished in size, that the teeth do not touch within one-sixteenth of an inch. He is right-handed, his tongue when protruded, points to the right; and during erection of the penis the organ points to the right side. From birth onwards the boy has enjoyed perfect health, but has preserved the same peculiar one-sided deformity in all stages of his growth. The present dimensions of the two sides are thus given at various points.—From sternum to spine round point of shoulder, left 13⅛ inches, right 11⅛ inches, length of left humerus 9¾ inches, right 9 inches. Whole arm, left 17⅜ inches, right 15¾ inches, circumference of fore arm, left 8⅜ inches, right 7⅜ inches. Whole leg, left 23¼ inches long, right 22 inches. Circumference of abdomen over umbilicus, left 13¼, right 12⅜ inches. Similar examples of a symmetrical development, though very rare, have been occasionally recorded, about a dozen cases being accessible. From a study of these it does not appear that one side is more frequently atrophied than the other. Dr. Pixley's is a well-marked instance of the deformity, and it is to be hoped it will be kept carefully in view in the future.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Halifax 12; Norwich 13; Bristol 15; Hull, Cardiff 16; Bradford, Wolverhampton 17; Birmingham, Brighton, Bolton 18; London, Edinburgh, Birkenhead 19; Plymouth, Portsmouth 20; Oldham, Derby, Leicester, Leeds, Huddersfield 21; Glasgow, Sheffield, Blackburn 22; Nottingham, Salford, Newcastle-on-Tyne 23; Dublin 24; Preston 25; Manchester, Sunderland 26; Liverpool 27.

Cholera-investigating Expeditions.

Professor Muenoh, of Kieff, has been sent to Egypt, by the Medical Council of St. Petersburgh, to inquire into the origin of the cholera, and make observations upon the course of the epidemic.

Germany is also sending a medical expedition, consisting of four members, to inquire into the causes, prevention, and cure of the disease. It left Berlin on the 16th inst., *viâ* Munich and Trieste, for Alexandria.

It is stated that the Chief Physician of the Khedive and Vice-President of the Egyptian Institute is satisfied that the present epidemic in Egypt is not Asiatic cholera, but *cholérоïde*, a local malady presenting similar symptoms.

A Sad Catastrophe.

Mr. Robert W. Corry, son of Mr. R. W. Corry, of Belfast, and nephew of Mr. J. P. Corry, M.P., who was drowned when on a botanising excursion in Lough Gill, held a high position as botanist at Cambridge, where he resided. He was one of the Lecturers on Botany in the Medical and Biological Schools. Early in the present year he was appointed Lecturer on Botany at Girton College, and was elected a Fellow of the Cambridge Philosophical Society. Lately he was awarded a supplementary science grant by the Royal Irish Academy, in addition to that granted last year, to aid in the completion of a botanical survey of the Ben Bulben Range, County Sligo.

A Disgraceful Possibility.

A discovery was made in Southwark last week of no less than eleven bodies of young children which had been stowed away in a neglected corner of premises in the occupation of an undertaker named Camden. These bodies appear to have been delivered over for burial by their parents, each of whom had made an insignificant money payment to the undertaker on the understanding that he would, in return, secure them decent burial. The scandal created by so gross a breach of confidence is not, however, the only, or even the worst feature of the occurrence, for an obstacle is now placed in the way of immediate interment of all the remains through the existence of those several difficulties of jurisdiction which are among the evils of London's existing government. Two only of the eleven bodies have as yet been disposed of, the coroner being unable to order the interment of the remaining nine because his authority does not extend to Bermondsey, the parish to which the parents of the children rightly belong. Consequently there arises a necessity for deciding by whom the task of burial shall be undertaken; and once more the public is treated to the unseemly spectacle of conflicting authorities in a dispute concerning their liability to discharge a pressing and paramount hygienic obligation. The frequency of such encounters is one of the most disgraceful possibilities associated with the municipal government of the metropolis; and it will be a measure of grateful relief that shall once and for all secure the non-recurrence of such indecent exhibitions in the future. Not only do they inflict a moral offence on the inhabitants of a great city, but they carry in their train dangers of the gravest public moment. The delay of a few days is often in such cases enough to determine serious mischief to the general health of a district subjected to a nuisance like that attendant on exposure of unburied human remains; and in every way it is highly desirable that efficient steps should speedily be taken for reforming the administration of districts wherein these scandals can be permitted.

New Sydenham Society.

The twenty-fifth annual meeting of this Society was held in Liverpool on the 3rd inst., when the report was presented and adopted, from which it appears that the production of the Lexicon of Medical Terms has been continued with as much speed as circumstances have permitted, and two numbers have, as usual, been issued during the year. The issue for the current year will probably consist of a fasciculus of the Atlas of Pathology; selections from the Works of Duchenne (of Boulogne), edited by Dr. Vivian Poore; two or more parts of the Lexicon of Medical Terms; the first volume of Hirsch's work on Historico-Geographical Pathology, translated by Dr. Creighton; a volume of Selected Monographs, of which Senator on Albuminuria and Landau on Movable Kidney will form part. The works which have been issued during the past (twenty-fourth) year are the following:—98. Stokes on Diseases of the Chest; 99. Atlas of Portraits of Skin Diseases, fasciculus xvi.; 100. The Collected Works of Dr. Warburton Begbie; 101. Lexicon of Medical Terms, part vii.; 102. Charcot, Localisation of Cerebral Disease; 103. Lexicon, part viii. Amongst those which are in preparation are—a fasciculus of the Atlas of Portraits of Skin Diseases; the Collected Works of Dr. Peacock, with memoir and portrait; one or more volumes of Selected Clinical Lectures from German sources.

Beer versus Water.

Advocates of the virtues of water as compared with those possessed by beer when employed as articles of diet during labour will be much chagrined at the result of a remarkable contest, waged on Friday last, with a view to determining the respective merits of the two beverages. The scene of this curious trial was a farm near Amesbury, in Wiltshire, where, under the auspices of the Church of England Temperance Society, two farmers competed against one another with a view to decide which could do the greatest amount of harvest work within a given time, one drinking beer and the other water during the contest. The arrangement was entered into at a public meeting at Salisbury, when Mr. Terrell, a Wiltshire farmer, and the champion of beer, challenged Mr. Abbey, an Oxfordshire farmer, and the champion of watar, to a day's labour, the stakes being £5 a side. At the end of the time "beer" was declared the winner by more than one acre, the surfaces cleared having been, by Mr. Terrell (beer), 15a. 3r. 16p.; by Mr. Abbey (water), 14a. 3r. 0p. It is of course to be assumed that all other circumstances were as nearly as could be equal on both sides, for otherwise it would hardly have occurred to the temperance advocate to suggest the competition; and this being admitted, an unmistakable victory would appear to have been secured by beer [over its opponent water as a supporter of stamina during labour.

Royal University of Ireland.

The Senate will shortly elect eight Medical Fellows, who will act as examiners at the examinations of the University. Of the eight Fellowships, five will be in Anatomy and Physiology, two in Surgery, and one in Medicine. The emoluments of these appointments will be £100 per annum each, and their tenure seven years. The election will be by open voting, and will take place some time in October.

The Chemical Manufacturers.

Messrs Robbins & Co. have published a reply to the statements of French authorities that bichloride of methylene, supposed to be of their manufacture, was a mixture of chloroform and alcohol. They repudiate the accusation, and give some details of their method of manufacture.

Mr. J. I. Atkinson, of Wylam-on-Tyne.

One of the most widely known and respected general practitioners in the North of England, Mr. John Ismay Atkinson, M.R.C.S., L.S.A., died on Wednesday last at his residence, Wylam-on-Tyne. For the last forty-four years the deceased surgeon had been engaged in practice in the same locality, and he enjoyed a high reputation throughout the whole district between Newcastle and Hexham as a skilful and kindly attendant, his services being in request in great houses as much as in humbler dwellings. The sincerity of the esteem felt towards him was shown but a few months ago, when he was presented with a brougham, a silver inkstand, and an illuminated address, which had been subscribed for by a large number of his patients and friends. His loss will be very widely regretted, and not least of all by the necessitous poor, to whom he was consistently and benevolently helpful, both in ministering to their ailments and to their more pressing needs. Mr. Atkinson was sixty-eight years of age, and until his last illness had enjoyed excellent health.

The Netley and London Army Examinations.

In reply to Mr. Acland, Lord Hartington stated in the House of Commons that the examination at the conclusion of the Netley course of instruction is, in the case of the Army Medical Department candidates, a pass examination merely, their relative precedence having been settled by the results of the entrance examination. With the Indian Army candidates the Netley course is competitive, and aids in determining the position of the candidates during subsequent service. The system for the British officers was deliberately adopted, after a very full inquiry, by a Committee appointed to consider the causes of the unsatisfactory supply of candidates for the Army Medical Service, and the Committee took evidence on this particular point. We have repeatedly referred to the fact that, while Indian medical officers are encouraged to work at Netley and pass out of that medical school in a state of the highest military efficiency, the medical officers of the home service are encouraged to neglect their study at Netley and to give themselves no trouble to learn their speciality. We have now for the first time from the lips of the Minister for War the admission that this distinction between the two services was made because it was considered that the trouble of study at Netley was one of "the causes of the unsatisfactory supply of candidates for the home service." In other words, idleness and ignorance are recognised by the authorities as an inducement to students to join the service. We do not in the least believe in the truth of such an hypothesis, but if it be as Lord Hartington says, we are decidedly of opinion that the Army authorities ought to blush at the admission that they seek to attract candidates by permitting them to pass into the service in ignorance of their own speciality.

The Queen's College, Belfast.

The report of the President, just issued, states that during the past session 533 students were enrolled in the various faculties, which include 300 in that of medicine. This latter faculty would have had a larger number of students entered were it not for a recent rule of the Royal University of Ireland, that all candidates for degrees in medicine shall be required, before being enrolled as medical students, to pass the first examination in Arts. The President suggests that the Royal University should follow the example in this respect of the University of London, by which examinations are appointed from time to time upon the application of any city, institution, or college desiring to be named as a local centre. The Council of the Belfast College at the commencement of the session resolved to admit women to art classes, and twelve young ladies were on application enrolled as students, ten of whom had previously matriculated in the Royal University. This is the first instance in which women have been admitted as students to a university college in Ireland.

The British Pharmaceutical Conference

Will be held at Southport, on September 18th and 19th, while its elder sister, the British Association, will be meeting in the New Dominion. Several gentlemen have already promised papers, and Dr. Attfield's presidential address will be on the Relations of the State to Pharmacy. The local committee are striving vigorously to make the three days at their disposal interesting and enjoyable to all concerned.

Death through Hydrophobia.

On the 15th instant an inquest was held at the workhouse infirmary, Callan, on the body of a labourer named Fogarty, who died from hydrophobia, as shown by the medical evidence given. Deceased was a native of Kilmoganny, and was bitten over twelve months ago by a dog supposed to be rabid. We hope to publish a report next week.

The French Association for the Advancement of Science

Opened its twelth session at Rouen on the 16th inst., the meeting being attended by great numbers. Medicine was chiefly represented by Prof. Verneuil. M. Masson, the treasurer of the Association, gave a flattering account of its financial position, its annual income and capital having greatly increased, while it was able to vote 13,000 fr. for scientific grants. Comparing the progress of this Association with that of the British, upon which it was modelled, M. Masson pointed out that the capital of the two Associations was nearly the same, although the British has reached the fifty-second year of its existence, while the French is only just entering upon its teens. And while the British Association only numbers 3,500, the French has already 4,000 adherents.

The Numerical Strength of the Profession in Paris.

The *Revue de Thérapeutique* gives an exact census taken of all the practitioners in Paris at the present time. There are in Paris and the communes of the department of the Seine 1,915 doctors of medicine, 12 doctors of surgery, 83 *officiers de santé*, 43 foreign doctors 1,500 midwives, 845 *pharmaciens*, and 95 veterinary doctors. One of the oldest doctors in Paris is M. Ricord, born in 1800, and made a doctor in 1826. These figures are, of course, exclusive of the host of illegal practitioners of all kinds to be found in Paris.

Telegraph Strain.

The *Boston Medical Journal* directs attention to the great demands made by telegraphy upon the nervous systems of those who follow it. The first-class operators all read by sound, and in a large office where a hundred or more receivers are all buzzing at once, the strain upon the organ of hearing, as well as upon the cerebral centre of audition, protracted as it is through ten hours daily, is very great. To discriminate between the longer and shorter dashes in an instrument clicking at the rate of a very large number of words per minute involves a very close exercise of the attention. The nervous and muscular energy expended by a rapid sender is very great. It is said that few operators are good for much after the age of thirty-eight.

A Milk Exhibition.

Amongst the very numerous departments of the Berlin Hygienic Exhibition, one is devoted to milk and the various products of it. Samples of fresh milk are daily on view, and we are told that the travelling "milk-halls" in which milk is sold are well patronised not only by women and children, but also by male adults. As every one knows, it is easy enough to exhibit samples of pure milk, and the exhibition will at least have the good result of letting the residents of a great city make the observation, at least during a brief period of their existence, what sort of a liquid milk really is. But the exhibition is doing more than this. Nearly every exhibitor exhibits by the side of his milk some form of milk-prover, some of which of late have been rendered tolerably perfect. That of Professor Soxhlet, of Munich, is constructed to show the fatty constituents of a sample of milk in a short time. Recknagel's lactodensimeter is also highly spoken of, as well as the lactobutyrometer of Marchand. Familiarity with these instruments cannot but have a good effect, as the employment of them will almost certainly become more general, and so falsified milk will be more certainly detected—and it is the difficulty of detecting falsifications hitherto that has led mainly to such wholesale adulteration.

In addition to the above exhibits of conserved milk are shown, and also attempts at preserving milk temporarily in as nearly a natural state as possible. Two methods adapted to this end are worthy of mention—one, that of cooling and keeping the milk cool by means of ice, and which one would imagine would add very considerably to the cost of transit; and that of Becker, of Düsseldorf. In Becker's process the milk is heated in a peculiarly-constructed water-bath to a temperature of about 140° F., and kept at this temperature for two hours. It is then covered up, but the circulation of air over it is not prevented. The results obtained are said to be remarkably good; the milk keeps sweet a long time, the taste of fresh milk is preserved, and when coagulated the curd forms an exceedingly loose and easily digestible coagulum, so that it is really superior as a food for infants to fresh cow's milk.

All the known kinds of preserved milk are shown, and also a new kind introduced by L. Scherff, of Berlin, which, from the account given of it, does not seem to differ materially from that known here as the Romanhorn brand—that is to say, it contains no added sugar.

Phosphate of Codeia.

Herr E. Merck, of Darmstadt, at the instance of Professor Hegar, of Freiburg, has succeeded in producing a phosphate of codeia, which has the great merit of being soluble in four parts of water, so that it can be used subcutaneously. It crystallises in small four-sided columns, is white, rather bitter to the taste, and resembles the sulphates and hydrochlorates of the same base. In its action it resembles morphia, except that it is milder, and the symptoms of intoxication are less pronounced. The dose required is about double that of the salts of morphia. No marked local disturbances followed the subcutaneous employment of the drug.

Nothnagel on the Treatment of Chorea.

In the course of a clinical lecture on chorea, Professor H. Nothnagel remarked that when the disease followed articular rheumatism, salicylate of soda was given; but this treatment had to be pursued empirically and carefully, as nothing was yet known of the nature of the disease. Opiates had no effect, neither had Calabar bean. Now-a-days potassic bromide was almost always given, but without any good result. As calmatives, and for the purpose of procuring sleep, morphia and chloral might be given. He had convinced himself by numerous experiments that propilamine was useless. Arsenic, in the form of Fowler's solution, was still the most effective remedy. It could be given by itself or in water. He suggested the following: ℞ Liq. Fowleri, grm. v.; aq. destill., grm. xv. M. Five drops to be given in a tumbler of water immediately after meals, and the dose to be increased by three drops every day until it reached thirty drops, after which it was to be slowly diminished. The constant current was another effective remedy in chorea, combined with tepid bathing, or the application of ice-bags to the spine.

Dr. Connolly, of Bruff, in the co. Limerick, and his brother, were arrested last week upon a charge of conspiracy to murder John Carroll, rent-warner to the Earl of Limerick, and his own relative. The charge rests on the information of another relative, who states that he was hired by Dr. Connolly to shoot Carroll, and lay in ambush with a pistol several times for the purpose, but that an opportunity for the crime did not present itself. Some time ago Dr. Connolly instituted an action of slander against Carroll, charging him with circulating a report that he, Dr. Connolly, intended to have him done away with. So far as the case has been investigated the evidence against the accused seems to be illusory.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 22, Bombay 28, Madras 34, Brussels 29, Amsterdam 19, Rotterdam 15, The Hague 30, Copenhagen 19, Stockholm 18, Christiania 21, St. Petersburg 28, Berlin 41, Hamburg (State) 21, Dresden 27, Breslau 28, Munich 40, Vienna 22, Prague 32, Buda-Pesth 28, Trieste 29, Turin 26, Lisbon 23, New York 45, Brooklyn 32, Philadelphia 25, Baltimore 27.

The principal zymotic diseases caused no death last week in Halifax, whereas they caused the greatest mortality in Sheffield and Preston. The highest death-rates from measles were 1·0 in Newcastle-upon-Tyne and 1·8 in Huddersfield; from scarlet fever, 1·5 in Leeds, and 1·8 in Sheffield; from whooping-cough, 1·4 both in Brighton and Plymouth; from fever 1·2 in Huddersfield; and from diarrhœa, 3·5 in Cardiff, 3·6 in Leicester, 3·7 in Sheffield, 3·8 in Salford, and 11·1 in Preston. The death-rate from diarrhœa, which was equal to 1·6 in London, averaged 2·5 in twenty-seven provincial towns. The 23 deaths from diphtheria in the large towns included 9 in London, 2 in Edinburgh, 3 in Glasgow, 1 in Dublin, 2 in Manchester, and 2 in Leeds. Small-pox caused 3 deaths in Birmingham, 3 in Liverpool, 2 in London, 2 in Sunderland, and 1 in Wolverhampton.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

Scottish Universities.—Pensions.—In our last impression we presented an epitome of the return moved for by Mr. Dalrymple with reference to the pensions of retired Scottish professors. At a time when the Universities are clamouring for more State aid, and fighting for what Mr. Mundella has so elegantly and appropriately termed their "beggarly vested interests," this return speaks volumes. Take, for example, the retiring allowance of Professor Allen Thomson, of Glasgow, at the age of 68, amounting to the large sum of £842 14s. 4d. per annum. No one who knows, as the writer does, anything of Professor Allen Thomson's teaching, will question his conspicuous gifts in the direction of imparting knowledge; but in return for all this, he was for a long series of years *protected by the Crown as a teacher of anatomy*, and during this long period derived a princely income from the position. Would it not, then, be fair and reasonable to expect that Dr. Thomson should have been able, in these circumstances, to make provision for what of life remained after the age of 68, without this very large drain on the public purse? The case of Dr. John B. Cowan is perhaps worse. An amiable, gentlemanly man, with a large private fortune, whose name, until his appointment to the chair at the University, was never heard of in connection with materia medica, Dr. Cowan intermittently lectured for three or four years on this subject, and retires at the age of 51 with a pension of £153 9s. 4d. In our opinion these pensions should certainly be reserved for necessitous, and not wealthy, professors; and the time has arrived when the whole matter should be subjected to radical public scrutiny. In no other department whatever have we State-instituted monopolies with such magnificent pensions; and to most sensible people, excluding ministers of a "liberal Government," it is a matter of no doubt that monopolies in scientific teaching are pernicious, and that the day has arrived when in science, as in everything else, the fittest should survive. It is quite possible that the Scotch professors are excellent teachers, but it is no disgrace to them to assert that they are better financiers.

Edinburgh.—New Hospital for Infectious Diseases.—A sub-committee of the Public Health Committee of the Edinburgh Town Council have had under consideration the subject of heating and ventilating the New Hospital for Infectious Diseases. Estimates had been taken for the work, but it was reported on the 23rd inst. that they were all much higher than the committee had anticipated. The subject was further delayed so as to allow the City Superintendent to make further inquiries, and, if necessary, go to Glasgow to inspect work of a similar kind which has recently been fitted up by the tradesmen of that city.

Edinburgh.—Public Health Committee.—A meeting of the Public Health Committee of the Edinburgh Town Council was held on the 23rd inst. The subject of the ventilation of water-closets into public stairs engaged attention, and in five cases of tenements in different parts of the city, which had been reported on by the Medical Officer of Health and Burgh Engineer, peremptory orders were given that ventilating shafts should be provided according to a plan suggested by the Burgh Engineer, and that the windows at present opening into the stair should be closed. Various unsanitary houses were reported on, and the owners called upon to show cause why they should not be shut up. These are situated at Castlehill, Lothian Street, and Clarence Street. It was intimated that complaint had been made from Warriston regarding offensive smells proceeding, it was supposed, from a tannery in that district; and of a nuisance in Blackford Crescent of a similar character, which, it was alleged, was caused by the proximity of a large block of stables, occupied by Messrs. Adamson, to the houses in the Crescent. The usual investigations were ordered to be made in both cases. As to the stables, it was reported that they had been visited, and that the premises were found in a cleanly and well-conducted state. Instructions were given that the heaps of stable manure collected should be restricted as much as possible. Two small cottages in Grange Loan were ordered to be closed, as the proprietor had taken no notice of the orders of the Town Council regarding them. A number of smoke nuisance cases were also considered. In the case of the Caledonian Distillery, several printing establishments in the New Town, and also mills along the Water of Leith, instructions were given to serve notices upon the owners. It was stated that in many cases where notice was served a marked improvement had afterwards been observed.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 18th inst., were at the rate of 22 per 1,000 per annum, as compared with 25 in the preceding week, and 22, 20, and 23 in the corresponding weeks of 1882, 1881, and 1880.

The Marshall Street Medical School, Edinburgh.—This, which forms one of the sub-divisions of the Extra-Mural School has come to an untimely end. The lecturers with one exception, together with the acting and honorary medical officers of the provident dispensary attached to the school, have all resigned. The existence of the place was only due to the want of interest which the Colleges till lately took in the internal arrangements of the Medical School.

Dundee.—Royal Lunatic Asylum.—An adjourned meeting of the directors of the Dundee Royal Lunatic Asylum, in reference to the present embarrassed state of the finances of the institution, was held in Dundee on the 24th inst. Sir John Ogilvy, the chairman of the Board, presided. The Committee appointed at the meeting held on Friday last submitted the appeal which they proposed the directors should issue to the public with the view of relieving the Board out of its present difficulties. The appeal was approved of, and it was remitted to the treasurer and the secretary to issue it. The financial statement shows that the new house and the laying out of the grounds, with new furniture, cost no less than about £66,000; and as the directors had little or no available means but the old property, the institution is now in debt to the extent of fully £50,000, secured over its old and new properties, and of about £11,000 of unsecured claims and obligations. In the course of the appeal, it is set forth that the directors believe that if subscriptions or donations to the extent of not less than £12,000 were now available to pay off floating debt, they would be able to tide over present difficulties, and, as opportunities presented themselves, make available, by feuing, the old property towards payment of the secured debt.

Health of Edinburgh.—The following is a statement of the health of Edinburgh for July, presented on the 23rd inst. by the medical officer of health, Dr. Littlejohn:—The total number of deaths recorded in the city was 323, giving a death-rate of 16·52 per 1,000 of the estimated population. In the following table the number of deaths during the month of July in the last five years is given, with the rate per 1,000 in each:—

	1882.	1881.	1880.	1879.	1878.
Number of deaths ...	338	280	340	324	356
Rate per 1,000 ...	17·52	15·07	18·30	17·66	19·69

The average death-rate in the month of July for the five years preceding 1883 was 17·64, so that the death-rate for July of this year contrasts favourably with the average of the preceding five years. In the following table the number of deaths registered in each of the sub-divisions of the city is given, along with the rate per 1,000, both for the month now reported on, and for the corresponding month of last year:—

	New Town.	Old Town.	South Side.
Number of deaths ...	97	182	44
Rate per 1,000 ...	13·26	19·60	14·88
1882	12·20	23·89	10·24

As regards age, 102, or 31·58 per cent. of the whole deaths were registered as under 5 years; 138, or 42·72 per cent., between 5 and 60 years; and 83, or 25·69 per cent., above 60 years. The deaths from diseases of the chest amounted to 107, or 33·12 of the whole; while 35, or 10·83 per cent., were due to debility or old age. Diseases of a zymotic nature proved fatal in 31 cases, or 9·60 per cent. of the total mortality. Last year, in the same month, there were 128 deaths, or 37·86 per cent., under 5 years; 132 deaths between 5 and 60, or 39·05 per cent.; and 78 deaths above 60, or 23·07 per cent. of the total mortality. The deaths from chest diseases in July, 1882, numbered 118, or 33·43 per cent.; from debility and age, 37, or 10·94 per cent.; and 27 from zymotic diseases, or 7·69 per cent. With reference to the high death-rate in the southern suburbs, it is explained by the fact that of the total deaths 50 per cent. were those of people above 60 years of age—the figures being, under 5 years, 7 deaths, equal to 15·90 per cent.; between 5 and 60 years, 15 deaths, equal to 34·09; above 60 years, 50 per cent. There were 588 births registered during the month, giving a rate of 30·07 per 1,000 of the estimated population. The males numbered 302, and the females 286. Of the births, 43 were illegitimate. Infectious diseases: During the month there were 48 cases of infectious diseases reported in terms of sec. 208 of the Edinburgh and Municipal and Police Act, 1879. These comprise 320 cases of measles, 106 scarlatina, 39 typhoid fever, 17 diphtheria, and 1 typhus fever. Of the measles cases, 113 occurred in the New Town, 148 in the Old Town, and 59 in the southern suburbs. Of the scarlatina cases, 61 occurred in the New Town, 33 in the Old Town, and 12 in the southern suburbs. Of the typhoid fever cases, 18 occurred in the New Town, 12 in the Old Town, and 9 in the southern suburbs. Of the diphtheria cases, 8 occurred in the New Town, 8 in the Old Town, and 1 in the southern suburbs. The one typhus case was from the Old Town.

Health of Edinburgh and Leith.—The mortality in Edinburgh for the week ending with Saturday, the 18th inst., was 85, and the death-rate 19 per 1,000. There were 19 deaths under 1 year, and 28 above 60 years, of which 5 were above 80 years. Diseases of the chest accounted for 36 deaths, and zymotic causes for 5, of which 1 was due to fever, 1 to scarlatina, 2 to measles, and 1 to diphtheria. The intimations of these diseases were 4 fever, 20 scarlatina, and 38 measles. No fresh case of diphtheria was reported during the week. During the same period 16 deaths were registered in Leith, 9 of these being in the south and 7 in the north parish, and being equivalent to a death-rate of 13 per 1,000 per annum.

The Scotch Corporations.—A long-drawn sigh of relief on the part of the Corporations has followed the withdrawal of the Medical Amendment Bill, and for another year these bodies will be left to their own devices. We hope that the lessons taught them by the fierce struggle for existence through which they have passed may be of use; but it may have the effect of only confirming them in their old ways by the sense of security which their success in blocking the Bill has engendered. To one who has watched the conduct of the Corporations in relation to the Medical School, the sudden burst of affection of the former for the latter is amusing and instructive. We have all along maintained that the Medical School of Edinburgh had nothing to fear from the extinction of the Corporations; it might even be shown that the School would gain by their happy despatch. The Corporations have all along kept aloof from the School, happy only in taking the fees which the reputation of the School brought to their doors. That the College of Physicians will benefit from the teachings of the last few months there can be no doubt, but with regard to the College of Surgeons the prospect is by no means so hopeful. The internal organs of that august body are in a hopelessly diseased condition. The Fellows are voiceless, progress is impossible, and life all but extinct. Examinerships are for life, the President is elected by the Council, who have not yet learned that Queen Anne is dead, and the same body is in turn elected by the President. In the College of Physicians a most suitable candidate in every way for the presidential chair was rejected, as it was thought that his University connection might act injuriously to the College interests. The proud boast of the College of Surgeons that it is an examining and not a teaching body has been shown to be a delusion, and has very nearly led to its extinction. In the year of grace that has been granted to the Colleges something may be done, but we may suggest to the Extra-Mural Medical School the necessity for united action on their part, and not to trust too implicitly to those whose affectionate regard is only the outcome of their fear of their own extinction.

◆

Literature.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. (a)

We cannot tell how many volumes of this valuable Society we have been called on to notice, nor can we help observing how steadily each volume has increased in size. The present one reaches to more than 500 pages, and we notice at the end of it a supplementary report, of 54 pages, relating to the termination of all the cases which were described in the volumes, commencing with the first and ending with the thirty-first volume. This most arduous and useful proceeding, which was suggested by Dr. J. Hutchinson, has been carried out by the following gentlemen:—Drs. Barlow, Parker, Baxter, Beck, Goodhart, Walsham, Kesteven, Godlee, Turner, and Mr. Barker. The mode in which these gentlemen acted is described, but we need not enter into the details of this particular part of the volume, as we are sure any one who takes up the volume at all will be certain to read this portion of it first. It was to have been expected that many of the cases could not be traced to the final result—and this has occurred—but there are quite enough to satisfy the curiosity of the reader.

On former occasions we referred at considerable length to many of the cases detailed. But our space is more limited now, and a very general notice is all we can give. The first division, is taken up with Diseases of the Nervous System. In it we notice several cases of much interest. Thus, No. 2, by P. Gould, M.S., is a case of "Congenital Absence of Right Hemisphere of Cerebellum." It occurred in a man of 80, a gardener by occupation, but who never showed any symptoms during life which would lead to the idea that such a deficiency existed. What are we to make of such a case? Or how explain it? Has the cerebellum no function? Or no control over certain movements of the body? We cannot answer these questions. No. 3, by Dr. Sharkey, is entitled "Case of Simple Cyst in the Cerebellum." It was found in a man of 22, who, from the age of 12, had at times violent headaches. Four months before admission, however, he had got a very severe blow on the back of his head, and from that period the symptoms had become more constant and more marked. Finally, after several rigors attended with severe vomiting, the patient died. Besides the cyst in the cerebellum the ventricles were distended with serum. The way the author interprets this case seems to us very questionable. No doubt the cyst caused the headaches, and the sense of "bursting." These symptoms were most probably due to a sudden congestion of the parts round the cyst, but the constant pain, and the violent vomiting of the last four months of life were, we believe, due to the serum effused into the ventricles, which the post-mortem showed were distended. We think those pathologists mistaken who state that serous effusions of this kind cause no symptoms; we are as confident, as the nature of the subject allows, that they do, and what is of more consequence, that they can be recognised during life, and treated; and that the views advanced many years since by Abercrombie are absolutely correct. But this is not the place to enter farther on a discussion of the question.

No. 7, by W. H. White, M.D., is entitled "Hyperæmia and Hæmorrhages in the Medulla Oblongata causing Sudden

---

(a) "Transactions of the Pathological Society of London," Volume XXXIII. Comprising the Report of the Proceedings for the Session 1881-82. London: Smith Elder, & Co. 1882. Pp. 455.

Death, owing to the Implication of the Vagal Nucleus." We notice this communication, as it appears to us a very strange one. The author wishes to connect sudden death in children with a diseased state of the medulla oblongata and upper part of the spinal cord, and gives three cases in illustration; and then goes on to say (p. 16): "As a result of these investigations (that is, on the parts removed after death) I found that the sections from Cases 1 and 2 were healthy, but that there were obvious microscopical changes in those taken from Case 3." That is, as we read it, that out of three cases adduced to prove a point, two failed to do so; and yet the author argues as if all the cases went to prove his position. We would like to have some explanation of this apparent incongruity. But even if all the cases showed the same diseased state of the medulla we could not accept them. The cases are quite too vaguely given. Thus, Case 1 had "pyrexia and delirium," and "died in the course of a few hours." Then Case 2 was an out-patient attending for some trivial cough. "The mother said it died suddenly, and as I had not suspected this I made a post-mortem, but no evidence of disease or foul play was found." Surely, such scanty details could not satisfy any one; and then on the next page it is stated, as we said before, that the medulla was healthy in both cases!!! This entire communication will have, we consider, to be remodelled and described so as to be understood.

No. 11, by H. A. Lediard, is entitled "A Tumour of Dura Mater Pressing on Cord in the Cervical Region." We call attention to this interesting case which occurred in a man of 25, because it is so well, and at the same time so concisely detailed. Amongst the cases of the Organs of Respiration we would direct attention to No. 5, by F. Simon, M.D., entitled "Double Stenosis of the Upper Air Passages in a Case of Tumour of the Thyroid Gland, supposed to be Malignant." The diagnosis of this case was most obscure, and the symptoms became so urgent as to call for the opening of the trachea, which seems to have relieved one of the causes of dyspnœa, but left the other unrelieved. The enlarged thyroid had, by pressure, caused wasting of some of the muscles of the trachea. The age of the patient was 79, and he was seen in the first instance by Dr. Byers, of Belfast. This communication is one of some length, but will repay perusal. Amongst the cases of the Organs of Circulation we would draw attention to No. 8, by S. West, M.B., entitled "A Case of Acute Fatty Degeneration of the Heart after Rheumatic Fever; Vegetations on Valves; Rupture of Chordæ Tendinæ." This is a case of much interest, and occurred in a youth of only 16. We must say, however, that we think the disease was of longer standing than the author stated. The fever only confined the patient for one week to his bed, and he died two months subsequently; the heart which weighed 14 ounces, presented valvular disease, with dilated cavities, and fatty degeneration. It is hard to realise such a condition in so short a period. There was no pericarditis. We should like to have known the state of the liver, which was described as being enlarged during life. No. 10, by W. H. Broadbent, M.D., is entitled "Malignant Disease of the Pericardium." It occurred in a man of 23, and there was great obscurity about the diagnosis. But we must refer our readers to the details of this highly interesting case. In the Section on Diseases of the Organ of Digestion we observed a very elaborate paper by A. Sangster, M.B., on "Psoriasis of the Tongue." The author has collected from several sources 44 instances of the disease. One of these was a female. Half of them were smokers. This communication will well repay perusal. The next paper by S. Boyd, M.B., gives the details of two cases of "Rupture of the Œsophagus," most probably due to digestion. This special subject requires more light to be thrown upon it. We recollect reading an able paper by a Scotch gentleman on digestive process leading to rupture both of the œsophagus and stomach. If we recollect rightly he attributed the result to a post mortem effect of the digestive fluid. No. 3 by R. E. Carrington, M.D., is a detail of three cases of "Hour-glass Contraction of the Stomach." This is an important communication, for, though it is a rare affection, it is evident from the details given that any practitioner might meet it, and the diagnosis would surely be most obscure. Vomiting of a severe kind seems to have attended all the cases of which the previous history was known. On the other hand, in one of the cases this vomiting had occured eight years before death; but had then subsided, and it only recurred six months before the patient's death. No. 8 by J. Tyson, M.D., is entitled "Simple Stricture of Pylorus; Dilatation of Stomach; Fibroid of Uterus." We notice this case because we believe the pylorus was not diseased. This part is stated to have been "half an inch in diameter, but not thickened abnormally." Now half an inch, unless we entirely forget our anatomy, is the natural diameter; but always admits of considerable stretching. Dilatation of the stomach is known to occur without any constriction at the pyloric orifice, and we consider that such was the case here. No. 12 by N. Moore, M.D., is a very interesting case entitled "Upper part of descending Colon, showing a Perforated Ulcer from a case of Typhoid Fever." The patient was aged 20, and died about the fortieth day of fever, and there were two perforating ulcers in the colon. As the author observes this must be a very rare occurrence, and yet not without precedent. It is worthy of note that there were but three ulcers in the ileum, and all nearly healed. In the epidemic in which this case occured, out of 19 cases examined 6 had ulcers in the colon, that is, one in three. For ourselves, we believe that the implication of the colon is one for which we should ever be on our guard, as its presence adds seriously to the course of the disease. This case is followed by the detail of no less then 95 cases where an examination was made, and which occurred in Bartholomew's Hospital in the course of 14 years. It is a valuable communication. We notice that there were 18 cases of perforation out of 95; whilst in a few there was literally no ulceration, and only slight enlargement of Peyer's patches. In others there were but one or two ulcers. Have the conclusions which inevitably follow from such facts been considered? Is it not clear that typhoid fever may prove fatal without the presence of any lesions in the intestine, or at least such as would cause death, or do not such facts account, and, in the most satisfactory way, for the occurrence of cases which we are constantly meeting, that is, where the symptoms are typhoid like, but pass away after eight or ten days. Other very important points may be deduced from the facts stated above, but we cannot pursue them further here.

We had marked out for special notice several more of the communications contained in this volume. But owing to our space being run out we can only name them here. "Fourteen specimens of Hydro and pyosalpiiix," by Lawson Tait, A case of "Filarial Hæmato-chyluria," by Stephen MacKenzie, M D. This is an essay illustrated by engravings, and of much interest. Specimen of Bilharzia Hæmatobia, by G. Zancarol, M.D., Surgeon to the Greek Hospital, Alexandria. This is also illustrated by engravings, showing these creatures in the submucous tissues of the intestines and bladder.

Some very interesting cases of disease in the lower animals are also given; though we cannot notice them more here.

We think we have stated enough to induce our readers to get this volume, and study it for themselves. It will well repay the perusal

AN ATLAS OF ILLUSTRATIONS OF PATHOLOGY. (a)

The illustrations of the present part are four in number, and represent five objects—syphilitic and lardaceous disease of the liver; abscesses of the liver; papilloma of the gall bladder; cancer of the gall bladder, gall stones, with obstruction of the cystic duct; and cancer of the stomach extending to the cystic duct. The gall stones are coloured, and very numerous, but we would take exception to their colour. We have never seen gall stones of such a colour in a long pathological experience. With this exception, we have nothing but praise to bestow on these coloured plates, which are wonderfully good, and well worth the whole guinea subscription. They are a good working size, and quite fit for exhibition to an hospital class, which is more than can be said of the microscopic drawings of Lancereau's Atlas—the only other one which is available to the general practitioner. Dr. Goodhart's little treatise, modestly called a summary, is all that could be desired. Every medical man ought to belong to the Sydenham Society, and thus give its managers the opportunity of affording that value which can only be accomplished by extensive co-operation.

(a) "An Atlas of Illustrations of Pathology, compiled chiefly from original sources for the New Sydenham Society." *Fasciculus* V. Diseases of the Liver, chiefly of the Gall Bladder and of the larger Bile Ducts. With Pathological Summary by Dr. Goodhart.

◆

THE MEDICAL LANGUAGE OF ST. LUKE. (a)

The principal interest of the question as to the authorship of the treatises which are commonly attributed to St. Luke is, of course, of a religious rather than a medical character. Yet to a physician it has in addition this peculiar interest—that, if decided in favour of the view usually adopted, it is an instance of extra-professional work done by a physician, and that the most celebrated instance on record, and of work admittedly of the very highest importance and most influential bearing on the world's history. For whatever view may be taken in modern days as to the systems of doctrinal belief which have been grafted upon the events narrated, it must be universally admitted that those systems—and, therefore, those events—have exercised upon the world's history an influence to which nothing comparable can be found in all the annals of the globe.

Much doubt has been thrown by modern criticism on the accepted view of the authorship of the various treatises known to us under the names of the Evangelists. In particular, the most strenuous efforts have been made to bring down the dates of their composition to a much later period than has usually been assigned to them. And this view, that they are of a later date than that assigned, has been supported—not by any genuine verbal criticism, not by adducing any instances of terms or expressions to be found in their pages which are nevertheless known to be of later origin, but merely by showing that there are but few references to them in a class of writing where, in accordance with a preconceived theory, there ought to have been references to them, and extracts from them, had they been written by the authors to whom they are attributed; that is to say, had they been of the date assigned to them. The validity of this pre-conceived theory, that is in fact of the major premisses of the argument against their authorship, may be assailed on various grounds; of these perhaps one of the most important might be one of which the supporters of the usually received view might be loth to avail themselves, namely, that no such position was then accorded to these writings as that which has since been attributed to them, and that no special reason existed why reference should be made to them rather than to other compilations, or to verbal traditions of the life and sayings of Jesus. The attitude, however, of those who maintain the received view has hitherto, in presence of their assailants, been that of the apologist. They have defended their views, they have contested alike the premisses and the reasoning of their adversaries; but it has, we think, been reserved for Dr. Hobart, in the volume now before us, to carry the war into the enemy's camp, and deliver an independent and original attack on their position. The originality of this attack is that which gives it its interest in the eyes of medical men, and leads to our noticing this book in a medical journal. The Third Gospel and the Acts of the Apostles have been attributed to St. Luke, who is definitely spoken of in one of the Epistles of St. Paul as being a physician. It has occurred to Dr. Hobart that valuable light might be thrown on the question whether St. Luke was really the author of these treatises or not by a comparison of the writer's language, his peculiar terms and modes of expression, with those which are to be found in the strictly medical works of well known Greek physicians. Should it turn out on examination that there was any very definite and well-marked resemblance between this writer's language and that of the writers referred to, Hippocrates, Galen, Aretæus, &c., then the conclusion could hardly be resisted that the traditional view of the authorship was correct, and that the writer was indeed the companion of St. Paul's travels, and had personal knowledge of, and participation in, the events narrated in his later production; while of those detailed in the earlier he would have at least such knowledge as could be conveyed to him by the actual eye witnesses of the events which he himself disclaims anything more than a traditional acquaintance with. This most important investigation Dr. Hobart has carried through with an amount of care and pains sufficient to place him on a level with the most laborious of German word-critics. The twenty-one volumes of Kuhn's edition of Galen have been laboriously waded through, collated and referenced. Hippocrates, Aretæus, Dioscorides, have been no less patiently examined, and the result has been the bringing together of a weight of internal evidence and word-criticism, such as, we venture to say, no impartial judgment can set aside, to the effect that the mind of this writer was not only intimately acquainted with the terms of medical science, but also thoroughly imbued with medical ideas and modes of thought. The author brings out this line of thought with peculiar force in examining those portions of the narrative which speak of diseases and miracles of healing, showing that the Evangelist was well acquainted with the diseases he is describing, and refers to them in technical medical language such as could hardly have been employed by anyone who was not professionally conversant with medical matters. A writer of the present day who should use the term "to percuss" might be safely set down as a member of our craft; the expression δακτύλῳ προσψαύειν has a sound as genuinely medical as the other, it expresses in fact exactly our "palpation." "Diagnosis" is another similar term, actually itself used by the writer of the Acts, and that not as commonly used by the Greek physicians and ourselves in reference to a discrimination or recognition of diseases, but in reference to a legal cognition of an offence. In fact, as we would say in the slang of the present day, and as Dr. Hobart brings out in numberless instances, the writer of these treatises talked medical shop. But that is the very thing that no one but a physician would, or indeed, could do. A person not a physician might try, as we say, to air his medical knowledge if he happened to come across medical subjects, but assuredly if not a physician he would never talk medical shop on other occasions; the shop he would talk would be that of his own profession whatever it might happen to be.

The case thus made out by Dr. Hobart, and illustrated by an immense number of instances of medical terms, compared, with great labour and erudition, with the same terms as used by the Greek physicians, seems to us to prove beyond reasonable doubt that the author of these treatises was by profession a physician; and this being established, the correctness of the tradition which attributes them to the physician St. Luke, the companion of St Paul in his travels, follows as almost a necessary inference.

Dr. Hobart thinks that Luke accompanied Paul as his physician, and adduces arguments in support of the view that on each of three occasions when the former joined the latter, assuming now the authorship of the Acts of the Apostles as established, Paul had been suffering from serious illness, or was at the time in a state of ailing health. We are not sure that we quite go with our author here, at least as regards Paul's illness, for, as a matter of course, any professional aid that Luke could have offered his companion would have been only too gladly afforded when needed; but we are inclined to consider the frequent mention of Paul's ailments and ill-health as referring rather to a chronic disease than to any acute disorder; and we think that there are pretty plain indications that this disease was of a nature allied to catalepsy, resulting in trances, visions, &c., some of which, indeed, Paul himself speaks of as having occurred at a time when soul and body almost seemed separated as by some strong nervous convulsion. This, however, in no way detracts from the interest of the question discussed in this work.

Correspondence.

CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—At the request of professional friends I have been induced to republish my paper on "Cholera: its Nature, Pathology, and Successful Treatment," as placed before the general meeting of the British Medical Association, held in the University of Dublin, in August, 1867. In your last issue you were pleased to notice favourably my *brochure*, and to suggest as supplemental to my treatment the hypodermic injection of morphia. While I have had large experience of the wonderful effects of this drug in other nervous diseases, I have not deemed it indicated in cases of cholera. Indeed, I should fear its depressing influences here. In my general summary of treatment I did not go into details, as these were annexed to each case. But I was most anxious to impress the principle upon which I acted, namely, the clearing out of the *prima via*, not by purgative, but by mechanical means, so to say. This was effected in all cases by the administration of strong mustard emetics, and in most instances supplemented by an enema of sweet oil, turpentine, common salt, and any convenient medium, such as warm water, gruel, &c., as may be observed from a perusal of the cases I have detailed. I was guided in my resort to this secondary procedure by a persistency of the cramps after the free evacuation of the stomach. I valued also the aids of sinapisms to the abdomen, and a stimulating anodyne invariably given. Subsequently the free use of ice was invaluable.

(a) "A Proof from Internal Evidence that 'The Gospel according to St. Luke' and 'The Acts of the Apostles,' were written by the same person, and that the writer was a Medical Man." By the Rev. William Kirk Hobart, LL.D., Ex-Scholar, Trinity College, Dublin. Dublin: Hodges, Figgis & Co. London: Longmans, Green & Co.

The treatment, thus briefly and generally sketched out, was so uniformly successful that I feel convinced of its efficacy in this much-dreaded malady. You have properly, I think, approved of a strong tincture of mustard suggested and used by me, as being more reliable than the mustard of commerce. Yet I have never gone to a case without bringing amongst my *armamentaria* a canister of our best Irish mustard for external, or possibly internal use. The tincture may not be at hand, and may not be always good, whereas the genuine flour of the seeds may be trusted. Moreover, as I desired that my treatment might find a wide acceptance for the general good of humanity, I was willing, as far as possible, to popularise the remedies, yet with all becoming respect for our profession.

Yours, &c.,
P. C. Little, F.R.C.S.I., &c.

82 Amiens Street, Dublin,
Aug. 24, 1883.

COMEDONES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—For the past nine years I have been suffering from comedones on my face, and I have tried every known remedy, but without effect. I have tried hydrarg. bichlor., also sulphur lotions and sapo mollis and spirit. vini rect., equal parts, at night time, to be applied. I have removed the comedones again and again, but they reappear as bad as ever in a few days. I do not know what the cause can be, as I am very careful with my diet, avoiding anything that might prove indigestible. I am also a total abstainer. I pay particular attention to my bowels. I have also taken internally Easton's syrup, also dialysed iron and liq. arsenicalis. I am of a very nervous temperament, and suffer very much in cold weather from languid circulation. I have also tried Turkish baths.

I shall feel extremely obliged if you will kindly inform me in your next issue what you would advise me to do. Perhaps you may have heard of a case as obstinate as mine, and may know some remedy that has been successful. Kindly also say if there is any good work published on the treatment of comedones, and oblige,

Yours obediently,
An Old Reader.

◆

THE DEPTFORD VACCINATION CASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having personally investigated the six cases of alleged syphilitic inoculation through vaccination at Deptford, I read the article in the last issue of your impartial journal with great interest, and I beg to be permitted to make a few observations on the question.

I must unreservedly state that there cannot be a doubt in the mind of a careful inquirer that the vaccinifer and the vaccinated babies never suffered, nor are suffering, from the symptoms of inoculated syphilis, as the vaccination wounds, very backward in healing as they have been, the time of the appearance of eruption in all of them, their character and the constitutional disturbance they have suffered from, are totally at variance with such a groundless assertion. The fact that five had the same vaccinifer, an illegitimate baby, and one from a second case, was considered sufficient by the anti-vaccinators in the locality to raise the storm, misled as they were by Mr. Fisher. They held a crowded meeting on Thursday last, where resolutions were passed condemning vaccination. Such a state of affairs only shows how necessary it is to make full investigations into cases of complaint before the mischief is done and thereby allay popular excitement. Dr. Stevens, of the Local Government Board, did personally inquire into the cases, and reported his views to the board of guardians at their meeting on Wednesday last, condemnatory of Mr. Fisher as a parish surgeon. But in order to satisfy the public mind his report ought to have been published, and fuller inquiries made to show how far the mischief was attributable to vaccination. For all the children have suffered from eczema, more or less severe, and one was complicated with erysipelas during the first week of vaccination. Under these circumstances one does not feel inclined to look upon these cases as mere coincidences, and were the Local Government Board to make inquiries how the operations at the public vaccination station are conducted, what assistance—qualified or unqualified—the vaccinator gets from others, they would render useful service in the cause of vaccination.

I remain, Sir, yours, &c.,
Montague D. Makuna.

26 Charing Cross, S.W.,
25th August, 1883.

POOR-LAW SUPERANNUATION.

We last week announced—with much regret—that the Government had been obliged to drop the Poor-law Officers' Superannuation Bill for Ireland, finding it impossible, at the late period of the Session to give it a place on the agenda of the House of Commons which would admit of its being discussed before twelve. The disappointment which the miscarriage of legislation involves is all the greater because the measure was perfectly certain to pass if it could have been brought forward. The exertions of the Irish Medical Association and the Poor-law Officers' Association had obtained for it the support of all parties, and the influence of Mr. Herbert Gladstone and Mr. Meldon, M.P., had removed all difficulties in its way, saving the hindrance incident to the late period of the Session. The second reading had been carried against the opposition of Messrs Biggar, Leamy, Lalor, O'Kelly, and R. Power by an overwhelming majority, and the motion to go into Committee would have been as easily disposed of if the preceding business of the House had terminated before 12.30 midnight. We are not aware that the opponents of the measure pretended to be actuated by any principle. They of course contend for the right of the elected guardians to "larrup their own niggers" without restraint of any sort, and they hated the Bill simply because Mr. Herbert Gladstone and the Irish Local Government Board approved of it. The only amendment worthy of the name which was suggested was a proposition that a discretion should be left to the guardians to reduce the Civil Service rate of pension by one-fourth if they pleased to do so; but even this would not have satisfied the irreconcilables or ensured the passing of the Bill. Mr. Healy had an amendment the object of which was to postpone the operation of the Bill until April next, the explanation of which lies in the fact that the Poor-law guardians' elections take place in March, and, as he anticipated a large number of resignations of officers, and of consequent new appointments, he was anxious that his party should have the opportunity of packing the Boards of Guardians beforehand, so as to exclude all applicants not of the dominant politics and religion.

In the interest of the medical officers who have been anxiously waiting the passing of the Bill, we greatly regret the delay in making it law, but we are encouraged by the belief that, no matter what party may be in power, the Bill is certain to pass before long. The profession may be assured that the Irish Medical Association will not lose sight of it.

◆

Obituary.

DR. HENRY LOFTIE STONEY, OF DUBLIN.

We deeply regret to have to announce the untimely death of this gentlemen, which took place on Sunday afternoon last, after a brief illness, from hæmoptysis of obscure source. Dr. Stoney was a comparatively young man. He qualified as L.R.C.S.I. and M.D.Q.U.I. in 1861, and after a brilliant career as a Demonstrator of Anatomy and private teacher, he was appointed Ophthalmic Surgeon to the City of Dublin Hospital on the retirement of Dr. A. H. Jacob from that institution. His remarkable capacity for imparting knowledge and managing a class raised him to the first rank as a teacher of anatomy, and gained for him the position of Professor of Anatomy in the Carmichael College, which appointment becomes vacant by his decease.

◆

Medico-Parliamentary.

HOUSE OF COMMONS.—Tuesday, August 21st.

THE FIRE AT A LUNATIC ASYLUM.

Mr. Freshfield asked whether the Home Secretary's attention had been called to the fatal fire which took place a few days since in a private lunatic asylum at Southall; and if he would consider whether it should be made one of the conditions of the grant of licences to such establishments that all necessary means and appliances should be provided and maintained, and precautions taken for the prevention of fires and for the escape of the inmates in such establishments.

Mr. Hibbert said that the Home Secretary had drawn the attention of the Lunacy Commissioners to the unfortunate fire, although it was not in the right hon. gentleman's power to lay down any conditions as to the mode in which licences should be granted. The Lunacy Commissioners assured him, however, that their attention was constantly directed to the subject of precautions against fire in lunatic asylums, and never failed to urge the adoption of additional means for preventing outbreaks.

On Wednesday the order for the second reading of the Medical Act Amendment Bill was read and discharged.

Thursday, August 23rd.

THE CHOLERA.

Mr. D. Grant asked the Under-Secretary of State for Foreign Affairs whether his attention had been drawn to the facts that France had voted a sum of money and Germany had decided to send a scientific commission to Egypt to study and report upon the special conditions of the outbreak of cholera in that country; and whether the report from our own medical officers which was to be laid upon the table of the House would be of the ordinary character, or have some elements of scientific investigation and precision so as to be of value in our knowledge of the disease.

Lord E. Fitzmaurice: Yes, Sir, the facts are as stated by my hon. friend. Dr. Hunter has already full instructions to report, for the information of the Sanitary Department of the Local Government Board, on the character and origin of the disease, but I have forwarded a copy of the hon. member's question to him.

◆

Royal College of Surgeons in Ireland.—The following is the Pass List of candidates for the First Professional Examination under the New Scheme, viz.:—

Andrew W. M. Adair, Alfred A. Austin, Samuel Boake, James Bogan, Patrick T. Bolger, Louis Buggy, Alfred C. Burges, Thomas W. Carpendale, Percy G. Carte, Joseph Casey, Thomas F. Cashin, Austin S. Clutterbuck, Patrick D. Coen, William M. Colohan, Thomas M. Corbet, Edward Corcoran, Robert H. Cox, William B. Dick, Kildare D. B. Dobbs, Edward J. Dore, St. Leger J. Edmunson, Victor E. A. Fenton, Michael J. Geary, Thomas A. Goodchild, Thomas G. Goodman, William T. Greene, John J. Hall, John C. Hamilton, John W. Haughton, John M. Hayes, Francis H. Hill, John H. P. Holehan, Bartley H. Hopkins, Richard M. Hugo, Edmund J. Jacob, William A. Kelly, John F. Kennedy, Leonard Kidd, Thomas Ledlie, Thomas J. Lenehan, Sinclair A. Long, Frederick A. Malcolmson, Francis J. Martin, Henry J. Mathews, Charles D. McCarthy, Philip P. McDermott, Charles McDonnell, Jeremiah E. Nally, Samson H. Newland, John W. O'Brien, John P. O'Connell, Francis C. O'Donohoe, Denis J. O'Loughlin, Jeremiah O'Sullivan, Richard D. Pennefather, Pierce H. Power, Everard M. Power, Thomas D. McC. Pownall, Michael Riordan, William L. Ross, Thomas Rossiter, John A. Ryan, Thomas S. Silles, William T. Steele, Thomas H. Strangman, William J. Taylor, John Topping, David W. Turpin, Thomas Woodburne, Charles S. Woodwright, William H. E. Woodwright, Thomas H. Wilson, and Edward Yeates. Ten were stopped.

The following is the Pass List of candidates for the Second Professional Examination under the New Scheme, viz.:—

Edward W. Hamilton, Augustus H. G. Johnston, William A. Johnston, and Richard B. McCausland.

At the examination in General Education the following candidates were adjudged Certificates of Qualification. The names in the first and second classes are arranged in the order of merit:—

First Class.—Patrick Rowe (William Johnstone and John T. Kennedy equal), Henry M. Walker, Thomas J. MacMahon, (William P. Barter, Eugene Pentony, and William A. Pope equal), Edward Frazer (Edwin T. Cummings, Jeremiah J. Daly, John M. J. Downer, John E. Foster, and Aloysius Quigley, equal).

Second Class.—James H. Clendining, Benjamin Beamish (William J. Langley, William Kerr Lochhead, and Neal Nelson equal), (Stafford M. Cox, John Mulquen and William P. O'Meara equal), Richard W. Anderson, Samuel H. Browning, and Robert A. Flynn equal), (William Cremin and Peter O'Dwyer equal), Thomas S. Downer and James O'Reilly, equal).

Unclassed.—John W. Allen, William B. Allen, Shenston J. Bishop, John J. Byrnes, Philip H. Cook, James O'F. Malone, Joseph F. Manix, and John T. Ryan. Twenty were stopped.

The following candidates passed the required Examinations for the First Half of the Letters Testimonial, viz.:—

Barkley J. Acheson, George Bagot, Henry B. Betty, George Brown, John Francis (Frank Blake) Campbell, William G. Connor, George Davison, Julius Barry Delany, Patrick S. Donnellan, Cuthbert Eccles, John J. Esmond, Robert H. Fleming, Patrick J. Ford, Laurence Geoghegan, Robert Gloster, Frederick J. Greig, Robert T. Herron, Ernest R. Howe, Samuel Hornock, Michael Keatink, Patrick J. Keenan, Graham Kennedy, John Keys, Benjamin Lane, Alexander D. La Touche, Kenneth M. D. Mackay, John McFadden, William McManus, Edward McNalty, James Maguire, Barcroft C. Manly, Thomas D. Moore, Timothy A. Mulcahey, Marshall P. O'Donovan, Robert J. Reilly, Edmond A. Ryan, Jeremiah B. Ryan, Francis H. Sinclair, James H. Stewart, Richard H. Vereker, John J. Walsh, Augustus Westroppe and John Wood. Thirty-two were stopped.

The following candidates having passed the required Examinations for the Diploma, and taken the Declaration and signed the Roll, were admitted Licentiates, viz.:—

Frederick W. Allwright, George Browning, John J. Buggy, John V. Byrne, Alexander Carte, Robert H. Clement, William Clifford, Arthur Cole, George P. Cope, Richard J. D'Arcey, Samuel R. Deane, William Delahunt, Patrick Donnellan, Patrick Duff, John Foley, Thomas F. Griffin, Thomas G. H. Hall, Frederick S. Heuston, Andrew Hunter, Joseph P. Kelly, John M. P. Kennedy, Daniel Kenny, Nathaniel S. Manning, Jeremiah T. Martin, John Martin, Alfred H. Middleton, Thomas Moyles, Richard Murphy, Andrew J. O'Flanagan, Joseph A. Purdon, William H. B. Robinson, George F. Roughan, Bartholomew Russell, Robert W. Russell, William S. Sprent, Edward C. Stack, William L. Symes, and Charles W. Wynne. Thirteen were stopped.

British Medical Service.—The following is the list of the candidates for appointments as Surgeons in this Service who were successful at the competitive examination held in London on the 13th inst.:—

	Marks.		Marks.
Bradshaw, O. G. D. ..	2410	Henston, F. S. ..	2100
Kelly, M.	2375	Durant, R. J. A. ..	2055
Pinching, H. H. ..	2355	Gubbin, G. F.	2030
Geddes, R. J.	2350	Myles, J. P.	1980
Kelly, W.	2185	Lesly, R.	1975
O'Connell, D. V. ..	2170	Birch, H. P.	1975
Dodd, A.	2140	Braddell, M. O'D. ..	1880
Wilson, G.	2121	Donnett, J. J. C. ..	1870
Reid, J. M.	2105	Sloggett, H. M. ..	1845
Winter, T. B.	2105	Robinson, C. S. ..	1755

Indian Medical Service.—The following gentlemen were successful at the examination held on the 13th August at Burlington House:—

	Marks.		Marks.
Mr. J. J. Pratt ..	2475	Mr. C. J. Sarkies ..	2341
Dr. R. Shore	2410	Mr. W. B. Bannerman	2230
Mr. H. Thomson ..	2015		

Naval Medical Department.—At the competition for Commissions in the Medical Service of the Royal Navy, held on the 13th August and following days, in the Hall of the University of London, Burlington Gardens, the undermentioned gentlemen were the successful candidates :—

	Marks.		Marks.
Lea, F. J.	2150	Coolican, J. P. J. ..	1945
Rowland, T. C. ..	2125	Doyne, R. W.	1845
Morely, E. J.	2035	Dimsey, E. R.	1815
Macnamara, H. W. ..	2025	McDonnell, J. R. ..	1795
Whelan, J. H.	2010	Donovan, D. W. ..	1760
Bassett-Smith, P. W.	2000	Meikle, H.	1715
Canton, H.	1690

Notices to Correspondents.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

THE STUDENTS' NUMBER, 1883-84.—The annual educational number of this Journal will be published on Wednesday, September 19th. Deans, Registrars, and others connected with the various medical schools throughout the United Kingdom, will oblige by forwarding the latest prospectus and such other information as will assist the Editors in the compilation of this important number.

STAPHYLOMA asks : 1. Whether we recommend the Petty Sessions or Quarter Sessions as the Court in which he should sue parties in for fees in the case of cancelled tickets, the sums being small enough for Petty Sessions Court. 2. Whether there is a penalty attached to the issuing of tickets for medical relief by the wife of a member of the Dispensary Committee. 3. Can he recover his fee in law off a magistrate who called him out of his district to certify to the condition of a lunatic. "I consider the magistrate had a right to have called the medical officer of the district in which he was at the time, and if that medical officer was not available, I am aware he could compel my attendance. I rest my claim on the fact that he did not call the medical officer of the district in which he was at the time first."

[1. We recommend Quarter Sessions, because there is an appeal to a higher court, which is not allowed from Petty Sessions, besides that the judgment of the Chairman of Quarter Sessions is superior to that of the magistrates. 2. No penalty, but it is contrary to the regulations, and a ticket filled up by another person than the Committeeman or Warden may be disregarded. 3. You can recover your fee from the magistrate if you can prove that he called you as a matter of simple contract, but if he has not previously called the medical officer of the district, assuming him to be available at the time, you cannot, strictly speaking, be paid out of the rates.—ED.]

DR. GRAY.—The regret you express at the failure of the Bill is echoed on all sides, and ought to indicate a healthy determination to unite and overcome the interested opposition which has, practically, been the chief means of bringing about the result you deplore. Your suggestion is worth consideration at least.

L. P.—You may make trial of citrate of caffeine, from which good results have been obtained. It is an undoubted diuretic, and is to be depended upon in a majority of cases of cardiac dropsy. Dr. Southey's drainage tubes, when they can be employed, are much more satisfactory than the usual aspirator. By their use the tension is slowly reduced, a method which possesses obvious advantages.

CORONER FOR LONGFORD.—Your letter is in type, for publication in our next.

◆

Vacancies.

Cashel Union, Cashel Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, September 1.

Castlebar Union, Castlebar Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, September 8.

Central London Ophthalmic Hospital.—Assistant Surgeon. Applications to the Secretary on or before September 8.

Dursley Union.—Medical Officer. Salary, £80. Applications to the Clerk to the Guardians before September 12.

General Infirmary, Gloucester.—House Surgeon. Salary, £100, with board. Applications to the Secretary before September 1.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident Clinical Assistant. Applications to the Secretary on or before September 1.

Jersey Public Lunatic Asylum.—Superintendent Medical Officer. Salary, £250. Applications to the President of the Committee before September 1.

London Hospital.—Demonstrator of Practical Chemistry. Salary, £100, and a proportion of fees. Applications to the Warden before September 1.

Sheffield.—Medical Officer of Health. Salary, £500. Applications to the Chairman of the Health Committee before September 6.

St. Bartholomew's Hospital.—Assistant Physician. Applications to the Clerk before September 11.

West London Hospital, Hammersmith.—Assistant Physician. Applications to the Secretary on September 24.

Appointments.

BARFOOT, G. H., M.D. Lond., Acting Medical Officer to the Wirral Children's Hospital, Birkenhead.

BRANNIGAN, J. H., M.R.C.S., Assistant Medical Officer to the Workhouse, Liverpool Parish.

BROUGHTON, H. T., M.R.C.S., L.S.A. Lond., Medical Officer of Health for the Heckmondwike Urban Sanitary District.

BROWN, D., L.K.Q.C.P.I., M.R.C.S., Medical Officer for the Second District of the New Winchester Union.

BROWNE, T., L.F.P.S. Glas., Government Medical Officer for the District of Campbeltown, New South Wales.

BURTON, W. H., M.D., L.R.C.P.L., M.R.C.S., Health Officer for Lowan Shire, C. B., Victoria.

CLAY, C., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Fovant District of the Wilton Union.

DOWSON, W., M.A., M.B. Cantab., House Surgeon to the Salop Infirmary.

EWART, J., M.D., Physician to the Royal Alexandra Hospital for Sick Children, Brighton.

FULTON, J., M.D., L.F.P.S. Glas., Honorary Physician to the Melbourne Hospital.

GOWANS, W. B., M.B., C.M. Edin., House Surgeon to the County and City of Perth Infirmary.

GRIFFITHS, J. DE B., M.B., C.M. Dub., Assistant Medical Officer to the Melbourne Hospital.

GUNN, R. M., F.R.C.S., M.B., Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

LOANE, J., M.R.C.P. Ed., M.R.C.S., L.S.A. Lond., Assistant Medical Officer of Health for the Whitechapel District.

MOLE, R. B., L.R.C.P. Ed., M.R.C.S., Medical Officer to the Seventh District of the Liskeard Union.

OLPHERTS, J. W., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Downpatrick Dispensary District.

O'MEARA, F., M.R.C.S., Medical Officer to the Tydd St. Giles's District of the Wisbeach Union.

O'NEILL, J. L., Medical Officer to Emerald Street Dispensary, North Dublin Union.

PAGE, F. M., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Bitton District of the Keynsham Union.

POTTER, J. B., Consulting Obstetric Physician to the Western Dispensary.

SUTTON, F. W., M.R.C.S., L.S.A. Lond., Assistant Surgeon to the Royal Berks Hospital.

WILLIS, G. O., L.R.C.P. Ed., L.R.C.S. Ed., F.F.P.S. Glas., Medical Officer for the Greys District of the Henley Union.

Births.

COX.—August 12, at The Limes, Cottenham, Cambs., the wife of C. Hayden Cox, L.K.Q.C.P.I., L.R.C.S.I., of a daughter.

DUKE.—August 14, at Kennington Park Road, S.E., the wife of Maurice S. Duke, M.R.C.S., of a son.

HEPBURN.—August 18, at 3 Bridge Road, Hammersmith, W., the wife of John Hepburn, L.R.C.P., L.R.C.S., L.S.A. Lond., of a daughter

Marriages.

BRODIE—CALLENDER.—August 15, at Morningside Parish Church, Edinburgh, William Haig Brodie, M.B., C.M. Ed., to Gilliam, eldest daughter of John A. Callender, Esq., of Newcastle Terrace, Edinburgh.

BURTONSHAW—NICHOLLS.—August 18, at All Saints' Church, Haggerston, Thomas Burtonshaw, M.R.C.S., of De Beauvoir Road, to Emily Louisa, second daughter of Thomas W. Nicholls, of Kingsland Road, N.

GAFFNEY—GRIFFIN.—August 23, at Rathmines, Charles Burke Gaffney, L.K.Q.C.P., L.R.C.S.I., to Mary, only daughter of the late P. Griffin, Esq., formerly of Cork.

GRIFFIN—GRIFFIN.—August 14, at Kilkee Church, John Griffin, M.D., of Kilkee, to Amelia (Amy), eldest daughter of Robert Griffin, Esq., B.L., Kilbaha, co. Clare.

HINTON—CHERRY.—August 15, at Zion Chapel, Bedford, James Thomas Hinton, M.D., M.R.C.S., of High Street, Croydon, to Sarah, youngest daughter of Luke Cherry, Esq., Mayor of Bedford.

TRAPP—HARTE.—August 16, at the Parish of Blandford, Dorset, John Best Trapp, F.R.C.S., to Helen Maynard, daughter of the Rev. William Harte, late Rector of Blandford.

Deaths.

ATKINSON.—At West House, Wylam-upon-Tyne, John Ismay Atkinson, Surgeon, aged 67.

BRADLEY.—August 20, at his residence, Kells Grange, co. Kilkenny, Thomas Bradley, M.D., aged 74.

HENRY.—August 21, at Landow, of typhoid fever, John Dawson Henry, M.B., aged 25.

KITTSON.—August 12, at Ballyhorgan, co. Kerry, Edward Kittson, M.D., Nenagh.

MACDONALD.—August 18, at his residence, Gordon House, Horsham, Sussex, suddenly, John Alexander Macdonald, M.D.

SMITH.—August 17, at Edinburgh, John Alexander Smith, M.D., Treasurer to the Royal College of Physicians, Edinburgh, Secretary to the Royal Society of Antiquaries of Scotland.

THE CHARACTERS OF THE TEETH IN PERSONS OF THE ARTHRITIC DIATHESIS. (a)

By DYCE DUCKWORTH, M.D., F.R.C.P.,
Assistant Physician to St. Bartholomew's Hospital.

It is not much the fashion at the present day to study or allude to diathesis. The tendency of the teaching of the last quarter of a century has been to ignore them, and to trust more to precise physical methods in examining each individual, in order to elicit the facts of disease and the principles which should guide the treatment of it.

For myself, I had the singular fortune to be trained both in the school of physiognomical and diathetic research, in that of exact physical diagnosis, and I have always striven to employ both methods to the utmost. I believe that a right interpretation of morbid states and tendencies can only be gained by the conjoint and mutually corrective application of both these methods to the individual.

To those who have not had systematic training in diathetic study the matter is very much like a sealed book, and, without teaching, it will take, even with aptness for the study, well nigh a life time for the correct interpretation of the varied forms presented by the several diatheses, either in their pure or commingled conditions.

To study any one of them singly would be a vicious plan, and likely to lead to narrowness of view and untrue generalisations.

Each individual must be referred, as nearly as possible, to his exact diathetic position. This is often difficult, and often impossible. A clear conception of the type of each diathesis must first be gained, and then the measures of departure from this be gauged, and the influence of blended diathesis, or of any cross-taints, be noted. Let me illustrate this by simply alluding to an instance in which a person of scrofulous habit is cross-tainted with syphilis, or one in which there is a conjoint heredity of both struma and gout. To recognise such commingling there must first be known the types respectively presented by pure scrofula and pure gout, and the special manifestations of syphilitic virus must likewise be appreciated.

A diathesis is recognised by certain characteristics in the bodily conformation. These are special and peculiar in each form, and they are usually inherited, though they may, conceivably, be acquired.

With each conformation there exists also a special tendency and predisposition to disease, or a definite line upon which degenerative changes will most probably take place. Each diathesis has therefore its accompanying cachexia. This was the teaching of Laycock, of Edinburgh, my former preceptor, and one of the greatest and most philosophical physiognomists that ever lived.

Thus, if a diathetic or constitutional condition be recognised in an individual, one may generally rightly predicate the morbid or cachectic tendencies likely to supervene in the life history of that individual.

The recognition of a diathesis is attained by a study in detail of the several tissues of the body, so far as is possible, and regard must be had to the development of the different systems. The long conformation and the various portions of the cutaneous system naturally command the greatest attention, and amongst these have to be considered the teeth, which more particularly concern us at present.

It must be borne in mind that for one example which typifies any particular diathesis we meet with a dozen or more in which a blending or commingling with other constitutional or diathetic states occurs. This is exactly what might be expected. An ordinary inheritance is that of commingled diatheses, and it is only when the progenitors on both sides present the characters of one diathesis that we may look for a perfect development of any pure diathesis.

It, however, happens that in an individual the peculiarity of one parent or ancestor is inherited in a more prominent degree, just as in likeness of feature, or in mental character, one member of a family "takes after" one parent or ancestor, while another reproduces the likeness and qualities of the other. For one cannot doubt that these likenesses of feature and character have also as exactly reproduced counterparts in the several bodily tissues, with the same potential qualities as to evolution, and the same tendencies to break down in similar lines of decay. I assume this as an inevitable law, and daily experience confirms the truth of it.

(a) Read before the Odontological Society of Great Britain.

I have preferred to discuss the characters of the teeth in persons of the arthritic diathesis, rather than to speak about the teeth of the gouty only. I believe it is the case that there is a basic arthritic habit of body, or diathesis, and that from this issue at least two branches, the gouty and the rheumatic stocks. These two are not convertible: they are distinctly different, but they may commingle. One will not produce the other, and will not become evolved into the other.

Both of these branches are very largely prevalent in this country, the gouty one being certainly commoner within the geographical limits of England proper, and most common in the south of England. The rheumatic diathesis is more widely spread and more common than the gouty. London appears to be the headquarters, or centre, of gout, and more true, unequivocal, gouty disease is observed in this metropolis than anywhere else in the world. This is unquestionably true in spite of many pardonable and unpardonable errors of diagnosis. A most interesting question may be asked, and one to which no answer can be given, as to the time when the peculiarities now recognised as associated with the several diathesis, first manifested themselves. We have in this country, I suppose, as mixed a race as can be found anywhere in the world, and the commingling of every known habit of body have been going on amongst us for centuries. Such varied blendings, however, give small indications, except in cases where there is sufficient predominance of characters which may be referred to any one diathesis, or to compounds of it and some other. Hence, it is very important not to be too dogmatic in asserting of any one class that such and such characteristics *always* prevail. We must take note of the indications in each instance, and, from study of a large number of examples, we may gather knowledge as to the type common to the majority. It is in this manner that I have sought to supply to-night such information as I can give respecting the dentition in persons arthritically predisposed and affected.

Already, this session, a communication has been read to this Society by Dr. Alfred Carpenter, in which some very dogmatic statements were made as to the teeth in persons the subjects of gout. These opinions were challenged by several speakers in a subsequent debate upon the subject, and I also propose to discuss them as I proceed.

I regret that I have no sufficient number of facts to guide me to an opinion respecting the primary dentition of those inheriting gouty or rheumatic tendency. Such knowledge as I have warrants me in affirming that the evolution and development of the milk teeth in such children is, for the most part, very satisfactory, and in strong contrast with that observed in the children of strumous parentage.

Let it be noted, at once, that the inheritors of an arthritic constitution are in no way free from a possible strumous or syphilitic taint, and that they, equally with other children, may be the subjects of ill-development owing to rickets or other dentalising causes.

But, given a fair chance in the world, the fact remains, I believe, that primary dentition in such cases is eminently satisfactory, and about as good as can be desired.

Without reference to either primary or secondary dentition, Dr. Alfred Carpenter stated that "the effects of the gouty diathesis do not show themselves so markedly upon the teeth in early life as is the case with the syphilitic or the tubercular states." To this I agree. (*a*)

Dr. Carpenter proceeded further to state that "he believed the teeth decayed sooner in those who were descended from gouty parents; that they were more prone to caries, and especially liable to those peridental inflammations which ultimately lead to necrosis." (*a*)

To these statements I cannot at all agree. My experience supplies very different evidence.

I have paid particular attention to the condition of the teeth in at least 300 hospital patients, *who were the subjects of unequivocal gout in every degree*. (*a*) Amongst these were cases in which the disease was inherited in very varying degree, and in which it seemed to have been newly acquired. These observations, noted at the time in my books, formed part of a systematic study of the textural physiognomy of the gouty, and were made with no other object than to record exact facts relating to this matter. The main results of this inquiry might be summarised in a few words, and are to this effect, that the teeth of the gouty are remarkably strong, well-enamelled, enduring, and unusually free from decay. (*b*)

Laycock taught this five and twenty years ago, and the same facts, I am informed, were also demonstrated by his pupil, Mr. Jonathan Hutchinson. My friend and colleague, Mr. Coleman, tells me his experience fully confirms these statements.

So much then for the main features of the teeth of the gouty. Much more remains to be said. I find that the teeth are commonly large and regular. (*c*) The edges are smooth in the permanent set, not crenated in cases of pure arthritic constitution. It has been noted that there is a tendency for one or more of the incisor teeth in the lower jaw to be pushed forward in persons of the arthritic diathesis. To this irregularity Laycock gave the name of "buck teeth." I have frequently found this to be the case, but I am not prepared to affirm that such a condition is always significant of this particular habit of body, and I believe that it is not confined to such instances. Overcrowding is less common by far, in all cases, in the lower jaw than in the upper, and so there seems less reason for this ejection from the ranks in cases where, as in persons of good gouty constitution, there is no imperfect development of the inferior maxilla. These "buck" teeth may not be produced till middle life, and thus incisors that have once been well in rank come to be partly turned round, or pushed forward. I wish I could furnish an explanation of this occurrence. I can only call attention to a well-observed fact, and one, perhaps, not sufficiently recognised. Laycock was of opinion that this occurrence was more common in persons who presented signs of the *asthenic* arthritic diathesis. I think, however, that I have certainly observed it in cases of the sthenic form.

Overcrowding may occur with, perhaps, as much frequency as in other habits of body, much depending upon the maxillary development. It has been observed that the children of gouty inheritance are apt to grind their teeth during sleep, and this habit may go on into adult life or mature years So vigorous may this be that I have known the enamel, which is so strong in such persons, to be chipped and broken off by it. In colour the enamel is most commonly yellow, and white teeth are somewhat exceptional. The colour is apt to deepen a good deal in middle life. In texture it is very hard. The teeth are in every way vigorous and firmly planted, and if extraction has to be practised the operation is as formidable in these cases as it ever can be.

There is a remarkable tendency for the teeth to be worn down on their free surfaces, sometimes showing the pulp cavity. This is quite in strong contrast with what is met with in the teeth of persons not arthritically disposed. It is often supposed to be due to habits of pipe-smoking, but this is plainly not always the cause of it, and it is almost

---

(*a*) It is, of course, not possible to study the teeth of one's private patients as is done in a clinic; but my observation, so far as I have conducted it, in this sphere, fully confirms all the statements and opinions put forward in this paper.

(*a*) *Brit. Med. Journ.*, November 18, 1882, p. 984.

(*b*) "Gouty people generally are not more than others liable to decay of teeth and the consequent pain."—"Clinical Lectures and Essays, Sir James Paget, edit. 2, p. 372, 1879.

(*c*) I have sometimes observed that the teeth are small in size, though well-formed, regular, and strong, with yellow tint of enamel.

as commonly seen in women as in men. It is certainly not always due to grinding in sleep.

There is also a great proneness for tartar to collect upon the teeth. Dr. Copland noted long ago that such incrustation indicated a tendency to gouty affection. (a) If the teeth are not regularly and properly cleansed this accumulation may reach extraordinary proportions, and, even with due care, collections will form along the inner gingival edges of the lower incisors. I am not aware that there is any peculiar chemical difference in the tartar of the gouty person as compared with that met with in others, and I feel indisposed to assent to Dr. Alfred Carpenter's statement that "lithate of soda is deposited in the circumdental membrane, and produces those diseases of the teeth to which the gouty classes are especially liable." I dispute the fact that these classes are especially prone to dental diseases, and I know of no careful observations which have proved that lithic acid is deposited in the periosteum of the teeth. I have not been able to find any chemical reactions in the tartar from gouty teeth indicating the presence of lithic acid.

I have observed, in a good many instances, that *perfectly sound teeth* are apt to be shed in persons who inherit gouty constitution.

This is a remarkable fact. A process of alveolar absorption appears to induce this loosening, though how this absorption comes about I am unable to tell. The last instance in which I noted this occurrence was in a young man aged twenty-six. A sound lower incisor tooth had been cast off, and the gum was absorbed along with the associated alveolar process. The gums were generally retracted, but the teeth were strong, yellow, and well-enamelled. This man inherited gout, and had his first attack at the age of twenty-six. Amongst my gouty cases I find notes of several persons who have become prematurely edentulous, and of many who have lost several sound teeth, or suffered loss in this way, and also by complete decay. (b)

With respect to cases showing caries, and also much tartar accumulation, I find that the majority have been careless persons, and more or less intemperate, and the significance of this fact for me is, that such habits distinctly lead both to worse gout and to much of the dental caries. Temperate gouty persons—and there are large numbers of such people, in spite of common and prejudiced views to the contrary—have good, strong, and sound teeth as a rule. If they abuse their constitutions by intemperance they rapidly induce gouty cachexia. This is a very different matter from a gouty inheritance or predisposition, in which, with care, no overt or serious gouty trouble need necessarily supervene.

It is therefore an error to place all cases of gout in one category, and to affirm that in such instances one may naturally expect to find carious teeth and many other dental troubles.

There remains to be said something respecting tendency to decay in teeth in persons of the arthritic diathesis. Amongst these are to be noted many instances in which florid complexion, with dilated small vessels, together with other signs in the circulatory system, betoken the existence of the vascular or sanguine form. The corresponding cachexia is shown by a tendency to atheroma and degeneration of the blood-vessels. This, again leads to further tissue degeneration, and hence the teeth are prone to suffer from imperfect blood-supply, and thus to decay in such cases. It is in this way, I conceive, that a good deal of the alveolar absorption, loosening, and caries of teeth met with in these persons is to be explained. The trouble arises from a defect in nutrition, due to the outcome of vascular changes. These changes are not due to the arthritic proclivity, as such, but attach themselves only to certain members of the great arthritic family, to wit, those of the vascular or sanguine variety.

I cannot doubt that erroneous opinions respecting the teeth of persons who are gouty, or are rheumatic, in varying degree, have been formed because the fact of commingled diathesis has been unrecognised or ignored. An inheritance of scrofulous taint, together with arthritic disposition, will materially affect the development and life-history of every dental tissue, and the characters proper to each will prevail according to the degree of heredity of each. Strumous taint appears to affect the enamel very materially, and there is special tendency to decay, the teeth being irregular, ill-developed, more or less serrated at the edges, and dingy in colour.

Inherited syphilitic taint will likewise modify the growth and form of the teeth of the arthritic, in the well-known manner described by Hutchinson, though the evils wrought here, *cæteris paribus*, are mischievous in less degree than in the case of strumous diathesis similarly cross-tainted.

The characters of the teeth in persons of rheumatic habit of body are certainly less remarkable than those which are noted in the gouty. The several tissues of the body appear to be less impressed by the conditions which lead up to rheumatic tendency than is the case in gout. Yet, for the most part, there is much similarity, and I recognise amongst the features of rheumatic inheritance the presence of strong, hardy, and well-enamelled teeth as the rule. This is not remarkable if it be true that both gouty and rheumatic predispositions are referable to the great arthritic (basic) family. In each case, however, the intervention and modifying influences of cross-taint and mingled diathesis must be considered.

Of the functional troubles of the teeth suffered by the arthritic but little need be said.

Sir James Paget has well described the painful state experienced by gouty persons in which the teeth feel as if loosened and raised from their sockets, and are very tender when brought in contact—as if, he remarks, the alveolar periosteum was swollen. (a) This condition seldom lasts more than a day or two, and subsides without any marked effects. It may come on very suddenly, as is the habit with many gouty affections, and may generally be traced to cold or to some alimentary disturbance.

I think that I have observed a greater tendency in persons of this diathesis to suffer from radiating neuralgia, affecting many teeth in both upper and lower jaws, as the sequel to that form of severe nasal catarrh which is properly called *gravedo*, in which the cavities of the antra, the frontal, ethmoidal, and sphenoidal sinuses are involved. Teeth that have been stopped will commonly ache more than sound ones under these circumstances, but the pain is sometimes worst in the strongest and soundest teeth.

Retraction of the gums in an extreme degree seems to be generally associated with some measure of alveolar absorption, and much tartar is seen oftentimes on the exposed necks of the teeth. Amongst the poor such a state is seen in persons both of arthritic and of other dispositions. It is generally significant of gross neglect of the teeth; but those conditions of alveolar catarrh, osteoperiostitis, and loosening are also symptomatic of diabetic cachexia, and should lead to special investigation of the urine if other more obvious signs of the disease have not already been recognised.

It would be a matter of much interest to inquire into the condition of the teeth in countries where gouty disease is unknown. The best American authorities declare that they hardly ever see unequivocal gout, even in the practice of large cities. All the factors leading to its occurrence have not hitherto been present. They may come, and conspire to introduce it to generations yet to be born.

(a) "Dictionary of Medicine," vol. iii., p. 984.

(b) In a discussion which was held in the Dental Section of the International Medical Congress in 1831, upon the causes which led to alveolar absorption and loosening of teeth, I find that no allusion was made to the frequency of this affection in persons of gouty habit of body. I find amongst my cases one of a healthy old woman at eighty-two, who inherited gout from her father and paternal grandfather. She first became gouty herself at the age of seventy, and has now deposits of urate of soda. Between her sixtieth and seventieth year she lost many of her teeth, which were quite sound, and gradually became loose. She is now quite edentulous.

(a) *Op. cit.*, p. 372

Civilisation is not credited by dental surgeons with having brought blessings along with it for the development and life-history of the teeth—rather the reverse, indeed; but the progress of their science has done much to repair the ills incident to exposure to luxury. It is a great matter that the dental textures are studied in relation to their whole anatomy and physiology, and it will be an additional advance when the great doctrines of diathetic predisposition, and of scientific physiognomy, are carefully worked out and applied to practice. I venture to hope that in this brief communication I may have contributed something towards such a study, and may enlist the interest of dental surgeons in the subject.

◆

OBSERVATIONS ON PUERPERAL FEVER. (a)

By THOMAS MORE MADDEN, M.D., F.R.C.S.E., M.K. & Q.C.P.,

Obstetric Physician, Mater Misericordiæ Hospital; Physician, Hospital for Sick Children, Dublin; formerly Examiner in Midwifery, Queen's University, Ireland, &c.

Puerperal fever, or metria, has always been a favourite subject of obstetric controversy. Nor, as long as our Registration Returns show that some 5,500 women die each year in this country from an infective disease consequent on parturition, can it be superfluous to re-discuss its prevention and treatment. Between the years 1847 and 1880 no less than 44,306 deaths from metria alone were registered in England. To these must be added 120,140 fatal cases tabulated as the result of "childbirth and metria." In other words, within the comparatively short period mentioned 164,446 deaths have occurred in England from a specific septic puerperal disease, the very existence of which is now disputed by some eminent authorities. The statistics just referred to, and which do not include Ireland or Scotland, where metria is no less prevalent than in England, by no means, however, represent fully the fearful mortality occasioned by puerperal fever in this country. The majority of women amongst the poor have no medical assistance whatever during labour, being then dependent on the good offices of some friendly neighbour, or perhaps hardly less ignorant midwife. Under such circumstances it would be as reasonable to hope for any rational treatment in a case of metria as to expect an accurate statement of the cause of death in a fatal case of this kind.

At any rate, the Reports of the Registrar-General prove only too conclusively that we are, unfortunately, still very far from having arrived at that promised stamping out of puerperal septicæmia which some have anticipated from the great advance which has been made in the obstetric art of late years, especially the more rapid methods of delivery now generally practised and the antiseptic treatment of puerperal patients.

With regard to the pathology and nomenclature of metria, or so-called puerperal fever, the views of Dr. Atthill and Dr. Thorburn are practically identical, and may be taken as the authoritative statement of doctrines generally accepted on the subject. These views may be thus summarised:—1st. There is no such specific disease as puerperal fever. 2nd. Inoculation with septic matter introduced from without is the usual source of puerperal septicæmia. 3rd. That auto-infection with septic matter resulting from decomposition of retained clots, membranes or placental *debris*, or from vitiated lochial discharge, is the cause of another form of self-generated metria or sapræmia.

Dr. More Madden, however, believes in the specific character of puerperal fever, and holds that all cases of metria, however differently they may be named at different times, and whether they be epidemic or sporadic, are really instances of one disease variously modified by the circumstances under which it occurs, and especially by the constitutional condition of the patient, the intensity of the septicæmic intoxication, and the prevailing epidemic constitution of the atmosphere. The disease may undoubtedly arise in the puerperal patient from infection with the poison of other zymotic disorders, such as erysipelas, scarlatina, and typhus fevers. Moreover, it may also be introduced from without by hetro-inoculation with septic germs from another puerperal patient, or by auto-inoculation with self-generated septic matter.

Pathologists have very generally adopted the views of Dr. Burdon Sanderson as to the gradually increasing virulence of successive inoculations with the exudations of peritoneal inflammation, viz., that, if the exudation of a simple peritonitis be injected fresh into the peritoneum of another animal, the disease assumes a more intense form in the second than in the first, and so on, until at last a virus is obtained of the virulence of malignant peritonitis in the human subject. This gradual evolution from traumatic infectivity to the intensified virulence of malignant septicæmia is entirely in accordance with clinical experience. Most epidemics of malignant puerperal septicæmia may be traced back to a single case of sporadic puerperal fever. In the Dublin Lying-in Hospital it has been observed by Dr. More Madden and others that, before any severe epidemic of malignant puerperal fever, a few sporadic cases of metria occur at intervals in the wards. These cases are generally primarily of a mild type. Soon, however, they follow each other more closely, and at the same time the character of the disease becomes more and more malignant, until an epidemic prevails, in which hardly any recoveries occur, and which can only be arrested by the temporary closure of the institution. It would, therefore, be impossible to refer to the etiology of puerperal septicæmia without an allusion to the alleged influence of lying-in hospitals in the epidemic spread of this disease. For many years the writer had maintained himself, and had taught others, that it was more possible even in large institutions in which a number of puerperal women are aggregated together, by proper antiseptic and hygienic precautions, to obviate any fear of epidemic puerperal fever. Longer experience, however, he regrets to say, prevents his still holding that opinion. For many reasons, large maternity hospitals would be desirable were they only safe. And there can be no better managed or better officered institution of the kind than the great lying-in hospital of Dublin. But great as have been the benefits conferred by such institutions as this, many as have been the lives therein rescued from the perils of childbirth, as well as the utility of large maternity hospitals as centres of obstetric education, these advantages are more than counterbalanced by the fact that in all hospitals where a considerable number of puerperal women are aggregated there is necessarily created a puerperal atmosphere, in which the germs of septicæmia are developed with a rapidity, and too often attain a virulence, unknewn under other circumstances. Moreover, such institutions are not only themselves the favourite habitation of puerperal fever, to which those therein confined are peculiarly exposed, but also that they must be regarded as centres whence at certain intervals, and under certain conditions, the virus of metria radiates in occasional widespread outbreaks of epidemic puerperal disease.

Hence Dr. More Madden has perforce been converted to Dr. Evory Kennedy's views on this question, and he believes that the time has arrived when, in the interests of humanity, every one of the great maternity institutions referred to should be finally closed and replaced by an equivalent number of small cottage lying-in hospitals. If this were done, within a very short period the present high death-rate from epidemic puerperal disease would, in all reasonable probability, be greatly and permanently diminished.

Amongst the causes of puerperal fever referred to in this paper, attention is called to the possibility of traumatic infection in cases of laceration of the cervix uteri during labour. This is especially likely to occur where the injury has been caused by the premature application of the forceps, or by undue force in their employment before the full dilatation of the os uteri.

(a) Read before the British Medical Association, August, 1883.

The prevention, rather than the treatment, of puerperal fever should be an object of solicitude to the obstetric practitioner. It should therefore be a matter of primary importance to prepare before delivery, as far as possible, the constitution of every patient for the approaching critical time by due attention to her general hygienic condition and nutrition, and, above all, the administration of some ferruginous tonic, such as the tincture of the perchloride of iron, for a couple of months before confinement. After delivery the functions of the nurse are most important in the prevention of puerperal fever. Nor can too much stress be laid upon the absolute necessity of attention to the sanitary surroundings of the patient, as well as the most scrupulous personal cleanliness. Above all, we must insist on the removal, by frequent sponging and bi-daily tepid irrigations, of all lochial or other secretions the retention and decomposition of which might possibly give rise to auto-infection.

With regard to the prognosis in cases of puerperal fever, or as to its treatment, it would be impossible to make any useful observations, since both depend entirely on the particular type of the disease present in any case, whether sporadic or epidemic.

There can be no question as to the fatality of epidemic puerperal fever. But still we have improved materially in its management, or else its present type has become more amenable to treatment since the time when it was asserted by an eminent obstetrician that he would as soon be called to a case of hydrophobia as to one of puerperal fever; or even since, more recently, in the writer's hearing, the late Dr. Stokes told the Dublin Obstetrical Society that in his extensive experience of over forty years' practice, he had never seen a single case of puerperal fever in which the patient recovered.

Within Dr. More Madden's own experience the prevailing character of puerperal fever had changed repeatedly in successive epidemics. In his student days in the Rotunda Hospital puerperal peritonitis, or metroperitonitis, were the most usual forms of epidemic puerperal disease observed. Such cases were then appropriately treated by mercurials with opium, and free depletion by leeching, as many as from twenty to forty leeches being applied at a time to the abdomen. A few years later, when he became one of the medical staff of the same institution, the disease had altered from an inflammatory to a low typhoid character, with little local pain or tenderness, but marked by intense prostration, muttering delirium, and evident symptoms of blood poisoning. This form of metria, which has continued prevalent to the present time, obviously called for nutriment and stimulants, and it was many years since he had seen a case of puerperal fever in which any form of depletion whatever could be thought of. On the contrary, now the life of the patient generally depends on the exhibition of suitable nutrition and stimulants. Foremost amongst these was *turpentine*, and for his part he agreed with Dr. Brennan that turpentine was the remedy *par excellence* in the treatment of puerperal fever; and he advised its external employment by stupes, as well as its administration by the rectum and by the stomach as long as either would tolerate its use. Next to turpentine he believed in quinine in combination with minute doses of grey powder, dried soda, and Dover's powder, unless contraindicated by the irritability of stomach. In some cases the hyposulphites, and in others sulphurous acid, appeared to act effectually as depurating agents.

The form of puerperal septicæmia now most frequently met with is of a distinctly remittent character. In several instances of this kind under the author's care the fever was of a well marked type. More usually, however, there were daily matutinal remissions, the temperature and pulse in the second week of the illness sometimes falling each morning to little above normal, and again rising gradually throughout the afternoon until the former had reached 104° or even 105°, and the latter exceeding 120. In such cases our main reliance must be placed on the free use of quinine, given in three or four grain doses every third or fourth hour *ad effectum*, whilst its often marked depressant influence must at the same time be counteracted by suitable dietetic and stimulant treatment.

It is obviously all-important in the general treatment of puerperal fever to encourage as far as practicable the natural efforts to eliminate the septic poison from the system by the action, within due limits, of the the various excretory chanels, *i.e.*, the skin, bowels, and kidneys. At the same time, we must support the patient's strength, and meet all local complications by appropriate treatment.

Finally, whatever other treatment may be resorted to in such cases, the use of warm antiseptic inter-uterine injections (or preferably irrigations), for the purpose of thoroughly washing out septic exudations is essential in the treatment of puerperal septicæmia. Of these injections the best for this purpose is a very dilute iodised solution, or else one of Condy's fluid or well diluted carbolic acid, or where none of these are at hand, camomile tea, care being always taken to avoid the injurious consequences of undue force, or the entrance of air into the uterine sinuses.

WIESEN AS A HEALTH RESORT IN EARLY PHTHISIS, WITH DIRECTIONS FOR CLOTHING, DIET, AND EXERCISE IN THE SWISS ALPS DURING WINTER.

By A. T. TUCKER WISE, M.D.,

Formerly Visiting Physician to the Infirmary for Consumption, Margaret Street, Cavendish Square.

(Concluded from page 174.)

Chapter VIII.

The Drawbacks to High Altitude Stations.

The great drawback to these health resorts, as with many others in the South, is defective sanitation. As long as overcrowding does not take place, the cold and snow will, to a great extent, mitigate the evils of bad drainage and impure emanations; but when hotels get filled with a large number of visitors, many of whom may be in delicate health, the air within will not (except by artificial ventilation and good drainage) be free from the usual indoor impurities, as exhalations from the lungs and skin of organic matter, scales of epithelium, fibres of cotton, wool, wood, &c.; the products of combustion from gas, lamps, and candles; bacteria and fungi; and, what is, perhaps, more important still in the case of delicate lungs, the bacillus tuberculosis floating about in the air. Patients must therefore exercise their own discretion in opening windows and airing their rooms as much as possible. A fair quantity of fresh air can always be permitted to enter the bedrooms, according to the desire of the individual; but in dining-rooms, billiard, smoking, and conversation rooms the means of admitting pure air and providing for the escape of foul are very imperfect. Until appliances are introduced into the hotels to clean the air, warm, moisten, and medicate it if necessary, the high altitude stations can scarcely be designated "air-cure places," for most of the patient's time is spent indoors, where the conditions in some of the hotels are no better than at home—perhaps worse, if the house should be full of people.

The stoves also require looking after—firstly, to see that servants do not entirely close the valve which regulates the flue; and, secondly, to have a vessel containing water in the room to supply the air with moisture. The hand-basin half filled will answer the purpose very well.

The Föhn wind and changes in the weather cause a certain amount of annoyance and dissatisfaction, for it is not always calm and bright, and there is rather a dearth of amusements, Davos Platz excepted, which has a theatre and concert-room, bands, &c., and quite enough gaiety for invalids. It is almost essential that some special employment should be undertaken: languages can be studied, or the mind occupied with work of some sort. By this means time does not drag heavily, *ennui* is not experienced, and restoration to health is not retarded by dejection of spirits.

The travelling also has to be considered. Those who are in pretty fair health can make the journey in three days, either to St. Moritz, Davos, or Wiesen, and twenty-nine hours to Andermatt, but a longer time is recommended for those whose health does not admit of prolonged confinement in railway carriages. The journey may be broken at Paris or Brussels, Bâle, and Chûr.

On arrival there is very often a difficulty in sleeping for the first few nights, depending on the sudden rise to high regions. This can be met by remaining a few days at Chûr (1,936 ft.). The stay there will frequently help in training the system to the new conditions. It must not be forgotten that the altered form of bed may, in many instances, prevent sound and refreshing sleep. The wedge-shaped hair bolster can sometimes be removed with great advantage to the sleeper, and extra clothing be placed over the shoulders and upper part of the body, which is usually not covered by the eider-down quilt.

Great discomfort is frequently caused by chilblains during the winter time. To prevent these, walking exercise should be taken immediately after breakfast, and the endeavour be made to keep the feet warm throughout the day by this means. The parquet floors, although healthy and advantageous in many respects, are, in a great measure, the cause of cold feet and the source of chilblains.

What has been advanced as an objection to Alpine stations is the use of the German stove as a means of warming the interior of houses and hotels. The fault, however, does not lie so much with the ponderous German *Ofen* as with improper management in neglecting to provide sufficient ventilation for the rooms and moisture for the air. An improvement on these stoves are the steam reservoirs in use at the Kurhaus, Davos Platz, the admission of steam being under the control of the occupant of the room in which they are placed. This plan also raises the temperature without raising the "dew point," or, in popular language, "dries the air," creating a necessity for a small supply of watery vapour to render the atmosphere fit for healthy and agreeable respiration; for although dryness of the climate is one of the main features of the Swiss Alps, a limit can be reached beyond which a dessicating effect may be produced, and it is probable that many of the disagreeable issues attributed to the Föhn wind are brought about by a rather sudden increase of temperature within doors, accompanied by too low a percentage of relative humidity. Unless attention is at once directed to the warming arrangements, feelings of *malaise*, thirst, cough, dryness of nasal passages, and possibly hæmorrhages may be caused.

The introduction to the bright and calm winters of these regions is sometimes wet, raw, and unsettled. Many who venture to leave England before obtaining intelligence of the state of the weather to be found at the place they intend to visit will incur some risk if they make a hurried journey from fair weather to cold and wet. Acclimatisation has frequently been held up as a pre-requisite for visitors, but, as the winter is generally bright, calm, with dry cold and plenty of sun, the risk of arrival, even after the commencement of winter, is certainly not greater than during the autumnal raw cold, alternating with falls of snow, and wind. To become acclimatised for the best season of the year, and the one which is regarded as the "cure" period, requires no inurement during the worst season. The selection of an Alpine station should certainly be influenced by the opinion of physicians at home, even where the intention is entertained of returning for a second or third winter. Perhaps this may seem to be written in the interests of the medical profession, but those who have spent three or four seasons at Davos will have observed that some cases return again who would do better in a southern clime. An over-estimation of their own recuperative powers, or an enthusiastic belief in the potency of the charming Alpine climate to sweep away all maladies, is possibly the cause of an injudicious decision.

Children over three years of age do extremely well in the Alps, make healthy blood and muscle, gain flesh, and expand their chests. Under this age, it is doubtful if sufficient exercise can be taken by a child to ward off the cold, without being swathed to such an extent in furs and flannels as would impede the free motion of the limbs and thorax, so essential to development in childhood.

It is also a moot question whether some invalids should not quit the Alps immediately the end of the winter seems approaching, as the changeable weather, with wet roads, winds, &c., is likely to upset many of the benefits gained during the dry season. In this case, it would probably be well to go south, Lugano (982 ft.), Como (705 ft.), Nervi, Sorrento, &c.; but if spring has set in, the shores of Lac Léman (1,230 ft.) offer a fairly safe change. Thusis (2,448 ft.), Ragatz (1,709 ft.), Mels (1,637 ft.) are near; Soglio (3,569 ft.), in Val Bregaglia, situated on the slope, is spoken well of by Dr. Holland as a halting-place. A month might be spent at any of these, previous to returning home, provided the weather is fine, but it is well to be impressed with the necessity of the great personal care needed during this migratory period, especially with regard to clothing. Thick flannels, socks, &c., should not be dispensed with hastily, and it would be well to guard against the change from the calm regions by adopting outer garments of close texture, impervious to the chilling effects of wind.

In conclusion, it may not be superfluous to remind those interested, that the high cold regions are not yet proved to be the best for all early disease. The varieties of chest affections and the individual differences of affected persons denote that one general climatic panacea is quite inadmissible, and what may be a suitable climate for one case may prove of very little value to another. Whilst some misconception prevails on these points, cold mountain air will not receive the appreciation it merits. It would be inconsistent to contend that any particular health resort had not its drawbacks, but in spite of much misunderstanding and opposition, high altitude treatment is gaining ground with the medical profession, and will, no doubt, some day take its right place in climatic therapeutics. Time is needed for the subject to be well threshed out by advocates and opponents alike.

Clinical Records.

NORTH EASTERN HOSPITAL FOR CHILDREN.

Simple Cerebral Meningitis (?) Purulent Discharge from Right Nostril—Recovery.

Under the care of Dr. ARMAND SEMPLE.

[Notes by E. Tull. Trevor, Registrar.]

A. K., girl, æt. 14 months, admitted on the 3rd of February, 1883. For the last week has been sick. Mother noticed that five days ago the child began to squint. No history of a blow. Temperature at out-patients' department 99·2. Bowels are constipated. Child well-nourished, lies with its head drawn back. Heart and lungs normal. Internal strabismus on the right side. Pupils equal; react to light. Reflexes normal. Cries a good deal; does not take much notice of what is going on close to it. Not sick since admission. E. T., 102·4; R., 44; P., 144. Ordered—Hydrargyri cum creta, grana ij. statim, and ice bag.

4th.—Coughed a good deal in the night. Was sick once. Jerked arms and legs a good deal when moved. Squints, and lies with head retracted as before. M. T., 100·4; E. T., 100. No tache cerebrale. Breathing not irregular. Tongue white. Bowels open once.

5th.—Abdomen not retracted. No tache. Child a good deal flushed all over the body. M. T., 101; E. T., 101; R., 46; P., 126. Potassii bromidi, gr. ij.; Aquæ, ʒj., ter die.

8th.—Breathing rather irregular. Head drawn back. Takes food well. Sick once. Vomit consisted of the contents of the stomach. Pupils dilated, respond sluggishly to light. M. T., 99; E. T., 99·2; R., 32; P., 126.

9th.—About the same; drowsy all the day. Face flushed. M. T., 97·8; E. T., 98·4. Ordered—Hydrargyri cum. creta, granum ter die.

10th.—Child quiet. Head not so much retracted. Pupils not dilated. Abdomen normal. Bowels not open. Respiration and pulse regular. M. T., 99·1; E. T., 97·6.

11th.—Drowsy all day. Pupils dilated, respond to light. Head retracted. Discs normal when examined by ophthalmoscope. Head still retracted. M. T., 97; E. T., 97; R., 24; P., 114.

12th.—Slight twitching of limbs at times. Much thinner. Pupils less dilated than yesterday. M. T., 97·4; E. T., 99.

13th.—Sick four times. Hands and face hot and flushed. Takes nourishment well.

14th.—Sick once. Breathing irregular. Other symptoms the same. M. T., 98; E. T., 99.

15th.—Sick three times. M. T., 97·4; E. T., 97·8; R., 42; P., 126.

16th.—Sick three times. Hands twitched in the afternoon.

20th.—Sick once. Breathing jerky. M. T., 97·6; E. T., 99·2; R., 24; P., 150.

21st.—Losing flesh. Skin on abdomen shrivelled and inelastic.

22nd.—Bowels constipated. Hydrargyri cum. creta, grana iv., hâc nocte.

23rd.—Sick three times. Powder given yesterday had no effect. Ordered one grain of calomel.

24th.—Bowels open twice. Lies in the same condition with the head much retracted.

27th.—Pulse 150, fluttering. Alternate flushing and pallor of the face. Feet twitch.

March 1st.—Wrists strongly flexed. Feet twitch. Head retracted. E. T., 99·2.

8th.—In the same condition. Pupils normal; do not respond to light. Head not quite so much retracted. Fingers strongly flexed; thumb flexed across the palm of the hands. Breathing irregular. Face flushed. M. T., 98·4.

11th.—Takes food well. Cries a good deal when disturbed. Head retracted and shaken from side to side. Temperature normal.

20th.—Arms and legs rigid. Toes pointed. Hands clenched. The right leg is more rigid than the left. Cries when disturbed. E. T., 99·2.

22nd.—Pulse rapid. Sole of right foot was burned with hot water bottle some days since. Epidermis loose. Dressed with boracic acid ointment and boracic acid lotion. Child cries when disturbed. Takes its food well. Head retracted.

23rd.—Left leg scalded with hot water bottle. The skin seems very sensitive to heat, as the bottles were not very hot.

31st.—Breathes heavily. Fingers and wrists very strongly flexed, and the hands supinated. Legs drawn up. Sore on the left leg unhealthy in aspect. Eyes open with a fixed staring look. Head slightly retracted. Face flushed.

April 2nd.—Lies in a semi-conscious state. E. T., 101·2.

4th.—There has been for the last 36 hours some purulent discharge from the right nostril. Spastic condition of the limbs continues. M. T., 98·8; E. T., 99.

8th.—Very profuse discharge from the right nostril to-day.

11th.—Discharge from the nostril tinged with blood. Spastic condition of the limbs the same.

25th.—Child in the same state. Legs are flexed on the thighs, and thighs on the abdomen. Fingers, wrists, and elbows are strongly flexed. Head drawn back.

May 2nd.—Temperature normal. Child cries a good deal. Rigidity of both limbs as before.

7th.—No change. M. T., 98·4. E. T., 103·4.

8th.—Temperature normal.

10th.—Discharge from the nose has almost ceased. M. T., 97·2; E. T., 98·2.

12th.—Child has gained 1lb. in weight during the last week. The rigidity still marked, but to a much less degree. She is apparently blind; does not blink when a strong light is passed before the eyes, nor when the finger is held close to the eyes. M. T., 98·2; E. T., 98·2.

17th.—Rigidity not nearly so great. Fingers are still flexed. Legs not so much drawn up. Does not cry much. M. T., 98·6; E. T., 98.

24th.—Ice bag discontinued. M. T., 98·4; E. T., 98·4.

June 7th.—Rigidity almost disappeared. Child has gained 4 lbs. in weight in four weeks. M. T., 98; E. T., 99.

17th.—Discharged. Rigidity quite disappeared. Child gaining flesh. Head not retracted.

Remarks.—The temperature for the first week varied between 101 and normal. It then was normal, or nearly normal, for seven weeks, when there was an evening temperature of 101·2, followed in 36 hours by profuse purulent discharge from the nostril. The temperature fell next day and remained normal for five weeks, when it rose one evening only, to 103·4 for no apparent reason. No syphilitic or tubercular history to be obtained.

August 29th.—Child brought to the hospital wonderfully improved and apparently taking notice.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

England and the Cholera.—The following is the gist of the remarks made by M. Fauvel concerning England and the cholera in Egypt, which was referred to in our last French correspondence:—The all absorbing topic at the Académie de Médecine is cholera, and the learned professors were never more at their ease, and never more ready for discussion, as a splendid opportunity was afforded for making an all round attack on England, which employed its great influence in rendering vain all measures of protection so that her mercantile interests should not suffer. M. Fauvel could not find words enough to express his indignation at the conduct of the English officials in Egypt, who since their acquisition of the control of that country did all they could to hinder the work of the sanitary authorities. After sketching the origin of the epidemic and explaining the several measures taken by the different European powers to prevent its introduction, M. Fauvel concluded as he commenced, by throwing the whole blame on the English Government. Of course the sentiments which inspired the learned member were those of the majority of his *confrérés* for just now he that would wish to be considered to be endowed with extra patriotic feelings must commence by abusing *La perfide Albion*. Doctors like to be considered patriots, especially since the Republic came in, and the tribune of the Académie de Médecine is thought a fitting place for politico-medical speeches. It is to be hoped that in any case the learned gentleman's fears will prove unfounded and that *La belle France* will not be invaded by this terrible disease. If your humble correspondent dared to give a little word of advice he would respectfully suggest that instead of passing our time in fulminating against our neighbours, we paid more attention to our own sanitary arrangements, the country would have less fear of invasion. If the cholera comes to France it will make its *début* at Marseilles in all probability. The contagion of the malady is now put beyond all doubt, but it is also proved that its ravages are greatest in towns where sanitary precautions are neglected. Marseilles is a city very defective in this respect, the water is of the worst description, full of animal matter, and if not filtered highly dangerous for drinking purposes. The port runs up into the town and the smell from it in summer is insupportable as the sewers empty themselves into it, and there being no tide the water remains stagnant, emitting its effluvium far and wide. Paris, the "centre of civilisation," is not much better in this respect as far as the working quarters are concerned, and it has been admitted even by that august assembly the Académie de Médecine, that the recent epidemic of typhoid fever was mainly caused by the wat

Treatment of Simple Chancre by Heat.—A member from Lyons read a communication on the treatment of simple chancre by heat. As the results of his experiments he was led to consider that the employment of an elevated temperature was an excellent means of annihilating the virus. The author recommended that a hip bath should be given between 104° and 107° and borne for several hours. He believed that this treatment would suffice to destroy the virus in twenty-four hours. In any case it was certainly the best treatment of phagedænism, and those chancres complicated with phymosis that no dressing can attain. It is needless to add that the doctrine of M. Pasteur as to the cause of virulent diseases has suggested this treatment.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 5, 1883.

FEMALE DOCTORS FOR INDIA.

For a long time past a commendable desire has been evidenced among those who are familiar with the surroundings of Indian civilised life, to provide some means of remedying the deplorable misery experienced by the native female population when overtaken by illness. So strict are the prejudices of creed by which the lives of Indian women are regulated that they almost invariably prefer to suffer the worst evils of disease, to the extent even of death, rather than submit themselves to examination and treatment by a physician of the opposite sex. The difficulty arising in this connection is fully recognised by everyone possessed of any acquaintance with native manners and customs; and it has naturally served to excite an intense anxiety in the minds of philanthropic reformers, both at home and in our distant Eastern empire. The rise and progress of the modern movement for the education of women to become medical practitioners, the growth in the numbers of those seeking this mode of entering on the duties of professional life, and the absence of considerable prospects of success for such medical women at home, have served also to open up a vista of employment for them in honourable service as attendants on the vast numbers of Indian women who are now practically debarred from receiving any scientific treatment whatever.

It is estimated that India contains not less than one hundred millions of female inhabitants, out of a total population of two hundred and fifty millions; and the whole of this great host of women is, in time of sickness and trouble, subject to the assistance possible to be rendered by native midwives, the principal majority of whom, on the most absolute testimony of credible witnesses, are altogether incompetent to lend help in any circumstances other than those of the most ordinary cases of parturition.

With the knowledge of these primary important facts to influence us, it is with a feeling of relief that we view the energetic steps that are being taken to provide fully-qualified female doctors for duty in India. The question has found able and eloquent advocates here in Drs. Garrett-Anderson and Frances Hoggan and others, and is now, by the intervention of private munificence and State aid, about to be put to the most practical test that can be afforded for determining the amount of success possible to be achieved by the movement. For many years the Indian authorities have recognised the need of medical aid which might be availed of by native women without compelling them to violate the commands imposed upon their observance by religious scruples; and, as the only feasible means of supplying such assistance, a free encouragement has been given to the training of native nurses and midwives for duty among their compatriots. It must be evident, however, that the attainment of even a high degree of success in this direction could lead to nothing more considerable than a limited mitigation of the great evil complained of, for, thoroughly as it might be observed, the education of women to fit them for undertaking the duties comprehended under the titles they were to receive, could never result in qualifying them as practitioners of medicine; neither the learning nor the experience of physicians is theirs, or can ever become theirs, and hence they are useless as agents in the mitigation of those innumerable diseases under which inhabitants of tropical countries are doomed to suffer. But if, in place of educating women merely as nurses and midwives, the curriculum to which they may enter is extended in such a manner that the whole range of professional instruction is open to them, and they can and will profit by it in such manner that they can claim to be regarded as medical practitioners by right of acquired knowledge, then are they likely to prove invaluably useful as attendants on the multitudes of women whose principles, while obstinately preventing their becoming the patients of male practitioners, do not in any way preclude them from freely submitting to treatment at the hands of doctors of the same sex as themselves.

By force of continued perseverance on the part of a few determined reformers, the medical classes of Madras were thrown open to women in 1874; and now, after prolonged agitation, the same concession is made in connection with the Calcutta Medical College. It is highly creditable, moreover, that the principal advocates of this liberal action themselves most vigorously opposed a resolution in favour of lowering the standard of preliminary examination to be passed by female students. To take such a step as this would have been to hazard the future success of the movement; and the absence of any necessity for it has been often and amply shown by the facility with which women have obtained the premier positions in competitive examinations to which they have entered on an equality with male students. The action of the Lieutenant-Governor in opening the Calcutta School to women has now finally removed a grievance under which Bengalee ladies have suffered in the past, the existence of the restriction which forbade them to pursue their studies in Calcutta having compelled their migration to Madras, whose doors have, as stated above, been open to them since 1874. That good use has been made by the ladies of the Calcutta classes of their opportunities is abundantly shown by the fact that one of them obtained the highest honours in the London University M.B. examination recently, while two others are holding valuable Government appointments as medical officers in Hyderabad and Rajpootana.

It is right that we should in this place correct the impression conveyed in a late number of the *Medical Press and Circular* to the effect that a lady-doctor at Hyderabad, the one mentioned above, was a failure, because, in an emergency, Sir Salar Yung had summoned a Bombay physician to see his wife, who was ordinarily attended by the lady in question. We are authoritatively informed that this consultant, though called at a great pecuniary cost, was not permitted to see the patient, but was only allowed to hold consultation with the female physician, and he was naturally much annoyed at having travelled so far to discharge a service which, he considered, might fully as well have been rendered by letter. We are glad to make this correction, because there was a general feeling, as we know, fostered by the imperfect account of the transaction, that in this instance, at least, native faith in even a highly-qualified female physician had not been proof against temptation to overthrow caste and call in the help of a man-doctor. Had the facts been as first reported they must have weakened the position of the reforming party. As they are now known to be, they serve to materially strength en it.

Dr. Frances Hoggan, who has prominently advocated the employment of women as physicians to native Indians, is anxious to see the movement receive official sanction by the creation of a State service of such practitioners, to be maintained by payments out of a special fund set apart for the purpose. For the present, however, this scheme has been permitted to give place to one in which private enterprise is mainly active, and as a result of which two ladies will proceed to India in November next with the guarantee, respectively, of £500 and £300 per annum, with free rooms. A fund has been raised for the establishment of a dispensary in Bombay, to which these ladies will be appointed, and it is anticipated that a hospital will also be speedily built to accommodate the most urgent cases applying for relief. Such a fulfilment of her most cherished aspirations must needs be eminently gratifying to Mrs. Hoggan and those who have so ably seconded her efforts to ameliorate the distressing condition of Indian women; and it is to be hoped that her philanthropic endeavours will meet with appropriate success. We cannot, however, forget the significant insistance of the native press of India on the first importance of sending out no lady doctors who are not *thoroughly well qualified* by education *and experience* to undertake the cure of the sick. Unless they can at once impress the native mind with the assurance of skill and competence to carry out the whole details of professional treatment, their mission will necessarily end in ignominious failure; and any such disaster should be most jealously and carefully guarded against by the exercise of due precautions in selecting fitting candidates for the posts. Dr. Frances Hoggan herself is clearly alive to the importance of this consideration; and we may confidently trust to her influence to prevent the introduction of any chance of failure in this connection. It would, however, be well if immediate attention were given by those in charge of the medical education of women in this country to the desirability of instructing such as look to future practice in India in a special knowledge of the diseases peculiar to tropical climates, and with which their experience will mainly be.

The enterprise is fairly floated. The object aimed at is one of mercy towards the millions whose situation loudly appeals to the sympathy of the benevolent; and the opportunity of effecting untold good in their behalf is associated with the solution of a problem which has for some time been assuming a serious aspect, that, namely, of providing remunerative employment for women-doctors. We wish the movement complete success, and, what is more, we feel that it will command it.

◆

THE FEEBLENESS OF THE PROFESSION IN PARLIAMENT.

The recent proceedings of Government and of Parliament in connection with the Medical Bill serve to illustrate markedly the political powerlessness of our profession which has recently been brought into prominence by Dr. Foster of Birmingham. We may remind our readers that medical reform has been agitated since the year 1867, when Lord Ripon took up the subject. Year after year the profession at large has clamoured for it out of Parliament with a vigour and unanimity which, if it had found expression in the House of Commons, or if it had had due influence with Ministers, would have long since forced the necessity for medico-educational improvement upon the serious attention of the public. Then the Duke of Richmond, being much importuned, took up the question, and an abortive select committee inquired into the facts, and at length, a Royal Commission of investigation having sat, the Bill was again presented to the Legislature. In a few weeks it made its way through the Lords, and for several successive months it hung fire, there being apparently not the least enthusiasm on the part of the Government to obtain its passing. Postponed from week to week in favour of measures of fourth-rate importance, it was at length presented for a second reading at the eleventh hour, and, even then, was dropped because the Minister would not trouble himself to negotiate for its passing. The Bill has, in fact, been sacrificed because the Government and Parliament did not care enough for it to give it a place amongst leading measures, and, when it needed a special effort to get it through the final stages, would not strain a point of Parliamentary custom and convenience to get it through the House. This narrative being interpreted means simply that Ministers do not care about doctors' wishes, because doctors' influence is not, politically speaking, worth anything. We suffer now, and have always suffered, the penalty of want of public spirit, of union, and of organisation, because our votes as electors are thrown away without exercising the least effect either on political or medical affairs. Our profession is possessed of at least 20,000 votes for Parliament, not to speak of its electoral power in municipalities and in local government, and in every constituency in the Kingdom it has a numerical strength which could make itself felt and feared if only that strength was exercised together. But it is never so exercised. Each medical voter records his vote simply as a political atom, and without considering or having the means of enforcing medical interests upon those who seek to represent him, and as a necessary consequence his opinions are entirely disregarded, and his vote goes for nothing. That this is so is manifest from the fact that at the second reading of the Medical Bill, while the Corporations who were interested in opposing the measure were represented by a solid phalanx of hostile Scotch and Irish members, and the Universities by an equally earnest band of representatives, the opinions of the rank and file of the profession were not embodied in the person of one single exponent, and, if the Bill had come on for discussion, we are not aware that there would have been even one member to speak for them. In fact, every M.P. feels, with reason, that the doctors in his constituency are good for only a few disjointed votes, and that even these votes are not dependent on medical considerations, and he therefore values medical opinion at the miserable political unimportance to which the indifference of the profession has relegated it.

We do not, of course, venture to suggest that great considerations of policy, party, and religion should be set aside in favour of medical interests; but we do urge that the medical voter should act upon the recollection that he is a doctor first and a politician secondarily. If Parliament be dissolved upon some question of overwhelming interest upon which the existence of a Ministry and a party depends, we can understand the medical voter sacrificing the opinions and interests of his own profession to the political necessities of the moment. But these crises occur seldom, and in the majority of elections the votes of the doctors exercise no political influence whatever, and would decide nothing. In these instances we say it is folly for medical men to throw their votes away upon the shibboleths of one party or another, when by throwing their influence into the scale they might at once secure pledges of support for medical legislation. We do not see the least difficulty in realising the political power of the profession which is now dormant. It would need only a central organisation, who could communicate with local branches in each constituency, and urge them to give their votes unitedly for those candidates who, *cæteris paribus*, would be the best men for medical interests. If those local branches interrogated the candidates before the polling day, and acted, so far as other considerations would allow, with unanimity in favour of the candidate who pledged himself to support their views, a new and overwhelming influence would be at once created which would raise our profession to a position of potency in Parliament which it has never yet dreamt of.

◆

DIET IN DIABETES.

Professor Ebstein, of Göttingen, in the *Aerzlich. Vereinsblatt*, May, 1883, discussed at some length the subject of diet in diabetes. Cantani's method of treatment is based on the opinion that the excretion of sugar in diabetics mounts constantly in direct proportion to the quantity of food consumed, even if it be wholly composed of flesh. He promulgates the law, the patient should not eat too freely if he is to avoid excreting sugar, but at the same time he should not eat too little, lest he die of inanition. In the choice of food Cantani permits all kinds of flesh, and places no restrictions on the mode of preparation, but every particle of starch and sugar is forbidden, as well as butter, as it contains a trace of sugar of milk. In the way of fat he recommends olive oil and all kinds of animal fats. He permits the largest possible quantities of the latter; to those who are thin, or whose digestive organs do not act normally, he recommends it pancreatised. M. Traube long ago demonstrated that diabetics actually digested the greater part of the fats consumed by them.

If the sugar does not disappear after the employment of a restricted exclusively meat diet—if loss of weight does not forbid—total abstinence from food for periods of from twenty-four to thirty-six hours is to be enjoined, a similar fasting to be undergone eight to fourteen days afterwards. The sugar then disappears. In cases in which total abstinence from food is not well borne Cantani gives three portions of meat broth *pro die*, each prepared from 400 grms. of meat.

Ebstein himself considers the most important point in the whole therapeutics of diabetes to be the limiting as much as possible of the quantity of food consumed. The patient should, however, suffer from feelings of hunger as little as possible. Both these objects can be attained by allowing large quantities of fat—the more, the thinner and weaker the patient is. Such treatment is not contra-indicated even in diabetes occurring in obese patients, for, says the writer, "If the diabetic treatment be carried on with intelligence, even in the case of fat patients, the excretion of sugar in the urine and the obesity of the patient will be seen to disappear with simultaneous increase of capacity for labour and bodily strength." Along with fresh meat and fats of good quality, in the proportion of two to one, he gives cabbage, leguminous vegetables, coffee, or tea (without milk or sugar), and at the most an average of 100 grms. of bread daily. Potatoes, sweets, and all kinds of starchy foods are absolutely excluded. He does not exclude butter, as Cantani does, as he does not, like him, fear the hydro-carbons. He further recommends lard, fat, meat-broths, or the marrow of bones. He has given up the substitutes for bread; the best of them he considers to be Seegen's improved Pavy's almond bread. He lays great stress on bodily movement and muscular activity. He has obtained good results from riding, but quite as good from passive muscular movements, such as massage, in which exertion on the part of the patient is avoided.

◆

Notes on Current Topics.

Prince Bismarck.

It is pretty well known that this illustrious Prince suffers much from violent neuralgias, which sometimes make their appearance as sciatica, and sometimes as tic douloureux. He is sometimes attacked by an inflammatory affection of the veins of the foot, as well as by ailments of various kinds, the results of colds and gastric disorders. It would, moreover, appear from the Berlin correspondent of our contemporary, the *Allgemeine Wiener Medizinische Zeitung*, that he has never cherished any feelings of regard for his medical attendants; at any rate, he has never given expression to them, and it has been his constant habit to dismiss them whenever the fancy took him. It has often enough happened that he has discharged a practitioner of ordinary medicine to take up with a "homœopath," and sometimes to have both kinds in attendance at the same time. As he has said, "The method of treatment is of less consequence to him than the result." Sometimes he has fixed a time for his attendant within which he has required to be cured, or at least rendered fit for work. If the result has met the requirement, the patient has been content, but he has never had a word of acknowledgment or thanks for his medical adviser. When he was Deputy in Frankfort he was attended by the then Regimentsarzt, now Director of the Imperial Health Office, Dr. Struck. When he was first in Friedrichsruhf, Dr. Cohn, of Hamburgh, was his attendant. When in Varzin he had a third. In Kissingen he consulted Dr. Diruf. His wife is a believer in homœopathy, as well as a trafficker in a nostrum (made from magpies' wings) for the cure of epilepsy, and for some reason—perhaps influenced by his wife—he was for several years under treatment by professors of the "School of Homœopathy." Three years ago he returned to the rationalists, and consulted Professor Frerichs, whom he had consulted many years before; but within a short time he had made another change, and called in the professional man under whose care he now is. The present favourite is a Dr. Schweningen, of Munich. This individual is a young man, 33 years of age, who, starting with brilliant prospects, has already succeeded in shutting himself out from relationships with most respectable families in consequence of some indiscretion in connection with the wife of another medical man, one result of which was that both parties suffered a term of imprisonment. Bismarck, however, requires only medicine from his doctor, and the young man found his moral, or immoral, behaviour no bar to the Prince's favour. With such a history before us, it requires no great effort to imagine that the "iron" Chancellor is not a very desirable patient; and those who are not the recipients of his favourable notice may console themselves when they see others preferred before them by the thought that, if the fortunate one is chosen to much honour, much is required to counterbalance the many disagreeables incident to the position of *Leibarzt* to one who knows not what consideration for others and gratitude are.

Removal of the Gall Bladder.

At a recent meeting of the German Surgical Congress in Berlin Dr. Langenbuch, of Berlin, showed a woman, aged 34, from whom he had removed the gall-bladder. The patient had suffered from gall-stones for nine months; the gall-bladder was felt as a hard, prominent, sensitive tumour. On opening the abdomen, the gall-bladder was found to be hypertrophied and adherent to the neighbouring tissues, and to contain a large number of stones, some of them adherent to the walls, and threatening perforation. The viscus was emptied by a Pravaz's syringe, and then easily detached behind the cystic duct; and the patient now looked well and blooming, although she had had a floating kidney removed in 1881.

Graduation of Surgical Knives.

A GRADUATED surgical knife has been devised by Dr. J. M. White, of New York. The graduations, or marks are etched on the sides near the back of the blade, and not on the cutting edge, so that the knife can be honed and strapped without removing the marks. They will indicate the depth and position of the point of the blade when it is plunged directly downward, also when the knife is held obliquely. The marks on the knife will show the depth of the incision in all cases, and are intended as a guide in deep incisions and shallow cutting operations.

Dr. Francis J. Falvey has been appointed by his Excellency the Lord Lieutenant of Ireland, Physician and Surgeon to the County Kerry Prison, in succession to Dr. W. H. Lawlor, resigned.

The Copper Craze.

For some time it almost appeared as though the advocacy of copper as a specific remedy against cholera was destined to obtain universal acceptance, and this in spite of contrary expressions of opinion occasionally evoked from unconvinced experimenters with the presumed antidote. M. Burg, however, of Paris, has so vigorously espoused the theory of prevention by copper, and apparently established its truth by an appeal to actual experience gained among *employés* in copper works during epidemics of cholera, that belief was growing in the protective influence of the metal to an extent almost as great as that felt in vaccination for small-pox. But at length the conclusions of M. Burg have been challenged by no less an authority than M. Bailly, who at a recent meeting of the French Academy of Medicine afforded personal testimony to disprove the copper-prevention theory. During the cholera epidemic of 1866, M. Bailly, whose practice lies among the workmen employed in manufactories where articles consisting mainly or wholly of copper are made, observed that many of these labourers were stricken down by the disease notwithstanding that they were constitutionally cupricised, and so, according to M. Burg, proof against choleraic attacks. In a similar way copper impregnation has not been found, in M. Bailly's experience, to prevent the onset of either typhoid fever or diarrhœa; and so much importance is deservedly attached to his communication that it is to become the subject of special consideration by a separate committee.

Exhibitions.

The incomparable success achieved by the International Fisheries Exhibition held this summer at South Kensington has induced the General Committee to consider the advisability of maintaining the costly buildings erected for the accommodation of the exhibits, with a view to their being utilised for international exhibitions connected with other industries. To this end powers have been sought for and granted, Her Majesty's Commissioners of 1851 consenting to extend the existing agreement (which expires Dec. 31, 1883) for three years longer, on condition the grounds are used solely for exhibition purposes. It is unquestionable that much benefit will accrue to the people generally from the holding of the Fisheries Exhibition; for not only has it given fresh impetus to the movement for supplying the poorer classes with an unlimited quantity of cheap, wholesome, and nutritious food, and so aided in overcoming such diseases as insufficient nutriment tends to induce, but it has also done much to popularise the consumption of fish by many who can advantageously adopt it as a frequent constituent of their dietary. Already arrangements are being contemplated for the next great international exhibition, which it is proposed shall have reference to horticulture, floriculture, and forestry.

The distinction of the Royal Red Cross, conferred by Her Majesty, was received on Friday last week at Chatham, for presentation to Miss J. King, Nursing Sister at Fort Pitt Hospital, in recognition of the devotion and competency displayed by that lady during the Egytian campaign.

The Progress of Dental Surgery.

At the recent meeting of the British Dental Association, held at Plymouth, the President, Mr. C. Spence Bate, F.R.S., took for the subject of his address "A Review of the Scientific Progress of Dental Surgery from 1771 to 1883." Commencing with a study of the inquiries initiated by Hunter, and on which modern dental surgery is principally based, Mr. Bate proceeded to sketch out the researches perfected by the chief authorities to whom the dental science of to-day is indebted for the foundations it rests upon. Some idea of the importance of the branch of surgery considered at the meeting is found in the fact, stated by Mr. Bate, that 20,000 ounces of fine gold are annually used in filling teeth. This, also, indicates the extent to which art steps in to affect the preservation of teeth, many of which, but for the perfected methods now in use by dentists, would sooner or later be absolutely destroyed and useless to their possessors. The cause of the rapid destruction of teeth in the present generation is assigned to the absence from them of lime; and this absence is attributed to the character of the food prepared for administration, more especially the vicious system of removing from wheaten flour all of those salts that are of importance to the human system. Mr. Bate employs words of caution to students not to mistake means for ends, and he thinks this tendency may be encouraged by a study of "some peculiar operations that were performed at the International Medical Congress." He should ever remember that "his duty in professional honour is to consider in all simpleness of purpose, before all things, the requirements of his patient."

Hospital Sunday Fund.

In a recent note on the Hospital Sunday Fund the deficit of the fund as compared with its amount last year at the same period was stated as being £4,000. This should have been £400, the actual decrease being reduced in amount as the returns are more perfectly made out. There is every reason to anticipate, as we are informed by the acting secretary to the fund, that by the end of the financial year, which terminates on October 31st next, the total receipts for the year will compare very favourably with those of 1882, when the disbursements to hospitals and dispensaries exceeded by £1,200 the sum distributed in any previous year.

Lady Medical Students at Madras.

The report of the Director of Public Instruction in India for 1881-2, and which has recently been received in this country, thus speaks of the progress made by female students in the medical department of the Madras University: "The lady students also are highly commended. The lady student in the senior department obtained 72 per cent. of aggregate marks at the professors' examinations. The others obtained an average of 73 per cent. Miss Kristy, a Christian Brahmin, acquitted herself well at all the examinations, and was awarded prizes for anatomy and materia medica." This satisfactory account of the advantage taken by ladies of the opportunities afforded to them of pursuing a medical curriculum is in itself sufficient justification of the course just adopted by the Lieutenant-Governor in opening the portals of the Calcutta University also to this class of students. That they are not slow to profit by what is offered them they have already shown. That they can find a wide sphere of usefulness in practising among native Indian women is conclusively demonstrated.

The London Hospital.

The ensuing winter session of the London Hospital Medical College will be inaugurated by an introductory address, which will be delivered on Tuesday, October 9, by Professor Huxley, F.R.C.S., President of the Royal Society. The proceedings will commence at eight o'clock in the evening; and following the conclusion of Mr. Huxley's address a *conversazione* will be held, at which past and present students of the hospital are invited to be present.

The Coombe Lying-in Hospital, Dublin.

Much disapprobation has been evoked in Dublin professional circles by the contemplated proceedings of the board of governors of the Coombe Lying-in Hospital, the effect of which, if persisted in, will be to oust the assistant physicians of the hospital from the position and emoluments .which they have earned during many years of past probation.

The seven years' service by Dr. Kidd as Master of the institution expired last month, and, according to the terms of its charter, its mastership cannot, under any circumstances, be held for a longer period. In view of the vacancy of the office, an election of a new master has been expected for some months past, but it was not held; and now it has become known that the governors have been moved by Lord Ardilaun to seek a Queen's letter to enable the charter to be overridden and a new lease of office given to the ex-master. It is hardly necessary for us to say that, if Dr. Kidd were a legitimate candidate, the hospital would be honoured by his presiding over it as chief of the medical staff; but he has served his term, and has nothing to gain for himself by a continuance in office, and the hospital will certainly not gain by making the mastership a chronic appointment. The inadvisability of doing so was decided upon when the charter was made, a few years ago, and we know of no valid reason for asking the Government to break through it, which we hope they will refuse to do. It would be a gross injustice to the assistant-physicians to deprive them of the promotion for which they have worked, and which—assuming them to be deserving—is virtually secured to them by the charter and by custom, and we say advisedly that a job of this sort will be as injurious to the character of the institution as of those who are mixed up with it.

We hear it rumoured also that it is contemplated by the governors to seize upon the instruction fees, which have heretofore been divided among the teaching staff of the hospital, and to throw these fees into the hospital maintenance fund. Such a transaction would be, in our opinion, not only monstrously unjust, but excessively foolish, for its direct and inevitable effect would be to destroy the teaching function of the hospital. The hospital has no claim to these fees; it does not pay the officers any remuneration worth talking of; but it accepts their gratuitous services for the inmates on the understanding that those services shall be to a certain extent remunerated by the instruction fees. Obstetricians and gynecologists of any rank worthy of consideration will not waste their time teaching if they have no remuneration therefor, nor will they trouble themselves with the work of an hospital which has no pupils to teach; and we fully expect, if this grasping policy be carried out by the governors, that before long the Coombe Lying-in Hospital will have ceased to exist as an educational centre, and will have descended—as an institution for the relief of the sick—to the level of a proprietary boarding-house for lying-in patients.

Egyptian Sanitation.

Dr. Hunter, in his report on the cholera epidemic in Egypt, says it is simply an abuse of words to talk of sanitation in connection with Cairo, every sanitary law being grossly set at defiance. The canals are little better than sewers, and no precautions deserving the name are taken to keep the source of the water supply from contamination. Conditions abound for the development and spread of disease in almost every form. In all essential features the cholera does not differ in type from that in India.

Interference in a Poor-law Election by a Medical Officer.

At a meeting of the Limerick Guardians, last week, a communication from the Local Government Board was read, which stated that they had received a report of the inquiry into the charges preferred against the medical officer of the workhouse of having interfered in the election of a guardian. It appeared that at the invitation of the chairman of the board, the medical officer accompanied him to the house of two clergymen. The object avowedly was to arrange an opposition, on political grounds, to the return of the complainant. Beyond introducing the chairman, the medical officer appears to have taken no part in the proceedings. Again, he appears to have visited the chapel. The object was to address the congregation, and this appears to have been well known to the medical officer, who attended to hear the speeches and see what took place. The medical officer swears that he had announced his determination of taking no part in the proceedings, on account of his position in the workhouse. He did take no actual part in the proceedings that day, but was unavoidably more or less mixed up with them outwardly. The only fair judgment, as it seems to the Local Government Board, that can be formed upon the medical officer's conduct in these transactions is, that he showed imprudence, and exposed himself to the suspicion of interfering, from private and self-interested motives, in a matter with which he had no legitimate concern. The impropriety of a paid officer taking any prominent or active part in matters affecting the constitution of the body under which he serves can scarcely be denied, and, if the medical officer had failed to recognise this obligation, he would have been liable to censure. But no evidence to this effect appears to have been produced at the inquiry.

The Irish Medical Directory.

The issue of this book for the year 1884 is now in preparation. The editor earnestly requests the members of the profession in Ireland who have not already done so to return to him, without delay, the circulars already forwarded to them, in order that accuracy may be secured. If medical men would only consider the trouble and expense which the re-issue of circulars involves, and the injury which a Directory sustains by the publication, year after year, of inaccuracies which are not remediable by any system of editing, they would not omit to take the infinitesimal trouble of returning their circulars. The editor especially solicits a note of any inaccuracy throughout the work which may be observed by readers.

The Telephone in Hospitals.

We are happy to learn that St. Vincent's Hospital, and the Meath Hospital and County Dublin Infirmary have been placed on the Telephone Exchange—a circumstance which will much increase the usefulness of these old-established and much-esteemed institutions. There are but few of the Dublin hospitals remaining unconnected, and we trust that they also will see the necessity of keeping abreast with the march of modern progress, and of not clinging too long to the ancient ways.

Prevention of Infectious Diseases.

At the Berlin Medical Society it was recently suggested that a fine should be imposed on parents who did not isolate their children when scarlatina or diphtheria was in the house. The difficulties of isolation among the poor were fully recognised, as also the uncertain state of medical knowledge with regard to the duration of the period of infection. Herr Goldsmidt stated that he had prevented the spread of scarlatina in a house by anointing his patients with lard, and then dusting on salicylic acid.

Anti-Vaccinators' Facts.

It will be recollected that within the closing days of the Parliamentary Session, Mr. P. Taylor, the Parliamentary exponent of the anti-vaccino-maniacs, put questions to Government as to the dissemination of syphilis by vaccination at Deptford. The assertion that disease was so disseminated was at once denied by the Minister who replied, but it is only now that the true facts have come out.

At the last meeting of the Greenwich guardians the dispensary committee reported that Dr. Kavanagh, public vaccinator, had brought a charge against Mr. Fisher, one of the district medical officers, of falsely certifying that several children were suffering from syphilis, and that the syphilitic disease was communicated through vaccination. The children in question (four in number) had been vaccinated along with seventeen others, and all the latter had presented arms of a normal character at the end of a week. Of the other four, one, specified by Mr. Fisher as suffering from syphilitic eczema, had a general eruption all over the body, which was completely cured after four days' treatment. Dr. Kavanagh had laid the cases before the Local Government Board, and had received from their inspector a letter, in which he said, "I think his (the district medical officer, Mr. Fisher) conduct truly scandalous, and he is, in my opinion, on that ground alone, totally unfit to hold his present office, not for his siding with anti-vaccinators, which he has a perfect right to do if he likes, but for his statement respecting the infant whose disease he entered as syphilis. This was either knowingly false, or believed to be true. If the latter, his ignorance shows him to be quite unfit for his post; if the former, dismissal is not enough punishment."

Health of Dublin.

According to the report for July, just issued by Dr. Cameron, Superintendent Medical Officer of Health for Dublin, the deaths within the metropolitan registration area amounted to 569, during the four weeks ended 28th July, 1883, and were in the ratio of 21·15 per 1,000 persons living. The deaths within the city were 467, and were in the annual ratio of 24·22 per 1,000. On the northen side the rate was 24·55, and on the southern 23·95. The deaths from the seven principal zymotics were in the ratio of 1·92 per 1000. As compared with the preceding month the deaths from whooping-cough decreased considerably. There was an increase in the number ef deaths from typhoid fever and diarrhœa. The zymotic death-rate decreased in the whole registration area from 2·02 to 1·92 per 1,000. As compared with the previous month there were large decreases in the number of admissions of persons affected with typhus fever, scarlet fever, and measles. There was a slight increase in the admissions of cases of typhoid fever. The total admissions of patients affected with the foregoing diseases averaged 13·25 weekly during July as compared with 17·5 in June and 31·8 in May. The following figures show the death-rate within the municipal or city districts:—1882.—May 28·94, June 23·22, July 22·1. 1883.—May 32·26, June 27·35, July 24·22. Death-rate from seven principal zymotics:—1882.—May 2·3, June 1·27, July 1·72. 1883.—May 2·88, June 2·5, July 2·4.

The Conversion of Malignant into Benign Tumours.

The celebrated Prof. von Nussbaum, of Munich, recently delivered a clinical address on the above subject, which has been published by Finsterlein, of that city. It was Thiersch who uttered the "weighty words"—"One ought not to despair of discovering a method of curing cancer if one could succeed in causing the proper remedy to act immediately on the structural elements for a sufficient length of time to prevent their proliferation without destroying them." Since many methods of treatment have already proved ineffectual, Nussbaum believes that he has discovered one that promises to fulfil the requirements of Thiersch, and which has, in fact, already shown good results. Nussbaum expresses himself thus: "It appears to me that the proper method of treatment is to cut off absolutely all the peripheral nutrient supply in order to keep proliferation in check without destruction of the tissues. The most suitable method of doing this is to draw a deep trench around the neoplasm by means of the thermocautery. The vessels that spring from the base of the tumour prevent its dying; they nourish it sufficiently, so that gangrene never takes place." The thermocautery is superior to the ligature formerly made use of by him. "I do not doubt," he says, "that this encircling of the tumour, this cutting off of all peripheral nutriment, has a future before it for those desperate cases in which hæmorrhages threaten to prove fatal, and in which the exhausted condition of the patient does not admit of amputation being considered. At any rate, the cutting off of the peripheral blood-supply leads to such surprisingly good results that I do not hesitate to recommend a trial of it."

Resorcin in Ozæna.

Drs. Masini and Massei, in the *Archiv. Ital. di Laringol.*, recommend the employment of resorcin in this troublesome and sometimes well-nigh intractable complaint. They recommend that the nasal cavity be first well washed out with water, after which a ½—1 per cent. solution of resorcin is to be applied twice daily by means of the spray apparatus, each application to be continued from three to four minutes. It may, if preferred, be used in the form of an ointment, and applied with a camel's hair pencil, the strength of the ointment to be about three per cent. In a proportion of the cases thus treated a cure was effected.

Hospital Saturday in London.

Last Saturday was appointed for the tenth annual collection in connection with the Hospital Saturday Fund. About 1,200 ladies, who had volunteered their services for the purpose, took up their stations in various parts of the metropolis at an early hour, the first to be at their posts being, of course, those at the markets and railway stations. It is anticipated that the result of the street collection on the present occasion will greatly exceed that of last year, when, although £2,500 was realised, the weather was of a very unfavourable character. Boxes were also placed in all the theatres and other places of amusement on Saturday evening as well as inside and outside the International Fisheries Exhibition. The instrumental concert in Victoria Park, which last year resulted in an addition of £80 to the fund, was repeated on Saturday evening, the experiment being also tried at Southwark Park. A collection was made on each of the vessels of the London Steamboat Company. Upwards of 36,000 collecting sheets and a large number of boxes have been forwarded to the workshops and factories of London for the purpose of this year's fund. At the conclusion of the collection the boxes were conveyed to Messrs. Hoare's bank, but the gross result will not be known until all the collecting sheets are returned.

The Pharmaceutical Society of Ireland have taken a house at 11 Harcourt Street, Dublin, as a provisional habitation for the society, which was obliged to leave the College of Physicians, as that body was unable to continue to give the requisite accommodation.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 33, Madras 32, Paris 22, Geneva 15, Brussels 26, Amsterdam 24, Rotterdam 17, The Hague 26, Copenhagen 22, Stockholm 24, Christiania 29, St. Petersburg 30, Berlin 32, Hamburg (State) 27, Dresden 23, Breslau 34, Munich 36, Vienna 22, Prague 30, Buda-Pesth 33, Trieste 24, Turin 18, Venice 28, Lisbon 30, New York 33, Brooklyn 33, Philadelphia 18, Baltimore 25.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Huddersfield 12; Bristol, Bradford, Plymouth 13; Halifax 14; Edinburgh, Birkenhead, Hull, Sunderland 15; Leicester, Bolton 16; Blackburn, London 17; Norwich, Brighton, Derby 18; Portsmouth, Cardiff, Nottingham 19; Dublin, Birmingham, Salford, Leeds 21; Sheffield, Oldham 22; Liverpool, Manchester 23; Wolverhampton 24; Glasgow 25; Newcastle-on-Tyne 27; Preston 30.

The lowest death-rates from the principal zymotic diseases were recorded last week in Bristol and Blackburn. The highest death-rates from measles were 1·4 in Brighton, and 4·5 in Newcastle-upon-Tyne; from scarlet fever, 2·0 in Birmingham, and 2·1 both in Leeds and Sheffield; from fever 1·0 in Leeds; and from diarrhœa, 3·8 in Salford, 4·4 in Leicester, 4·5 in Newcastle-upon-Tyne, and 4·4 in Preston. The death-rate from diarrhœa, which did not exceed 0·8 in London, averaged 2·3 in twenty-seven provincial towns. The 37 deaths from diphtheria in the large towns included 19 in London, 1 in Edinburgh, 6 in Glasgow, 2 in Leeds, 2 in Sheffield, and 2 in Cardiff. Small-pox caused 6 deaths in Birmingham, 2 in Liverpool, and 1 in London.

The Bill introduced by Government to make better provision for the prevention of outbreaks of formidable epidemic, endemic, or infectious diseases, gives to the local sanitary authorities in England and Ireland greater powers for borrowing money, if necessary, for the carrying out of regulations made for the following purposes:—For the speedy interment of the dead; for house to house visitation; for the provision of medical aid and hospital accommodation; for the promotion of cleansing, ventilation, and disinfection; and for the guarding against the spread of disease. The Public Health (Ireland) Act, 1878, is also amended so as to enable the Local Government Board to direct urban sanitary authorities to see to the execution of any regulations made by the Board, either independently or jointly with the Poor-law guardians.

◆

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

Edinburgh.—The University Extension Buildings.—Mr. Andrew Carnegie has added to his munificent benefactions to Scotland by intimating a subscription of £1,000 to the fund now being raised for the completion of the new Medical School of Edinburgh University.

Vital Statistics for Scotland.—From the return of births and deaths of the Registrar-General in the eight principal towns of Scotland for the week ending Saturday, August 25, we learn that the death-rate was 21·1 per thousand of estimated population. This rate is 1·1 above that for the corresponding week of last year, and 0·9 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 11·9 per thousand; and the highest in Paisley, viz., 30·7 per thousand. The mortality from the seven most familiar zymotic diseases was at the rate of 3·4 per thousand, or 0·4 below the rate for the previous week. Diarrhœa, scarlet fever, and whooping-cough were the most prevalent of the epidemic diseases, the mortality therefrom being most marked in Glasgow, where 6 deaths from diphtheria were also registered. Acute diseases of the chest caused 67 deaths, or 5 less than in the previous week. The mean temperature was 58·4, being 1·4 above that of the week immediately preceding, and 2·8 above that of the corresponding week of 1882.

EDINBURGH DEATH-RATE.—The mortality in Edinburgh for the week ending with Saturday the 25th ult. was 68, and the death-rate 15 per 1,000 per annum. There were 18 deaths under 1 year, and 17 above 60 years, 5 of which were above 80 years. Diseases of the chest accounted for 24 deaths, and zymotic causes for 5, of which 2 were due to fever, 1 to diphtheria, and 1 to measles—the intimations of the diseases being 8, 3, and 34 respectively. Of the 148 deaths registered 17 were illegitimate.

GLASGOW DEATH-RATE.—The deaths in Glasgow for the week ending with Saturday the 25th ult. were at the rate of 25 per 1,000, as compared with rates of 22 in the preceding week, and 20, 20, and 21 respectively for the corresponding weeks of 1882, 1881, and 1880.

THE CHAIR OF MEDICAL JURISPRUDENCE IN THE UNIVERSITY OF ABERDEEN.—A meeting of the Aberdeen University Court was held last week for the purpose of appointing a successor to Dr. Ogston, senior, in the professorship of Medical Jurisprudence. The candidates were:—Robert Beveridge, A.M., M.B., Aberdeen; Angus Fraser, A.M., M.D., Aberdeen; Matthew Hay, M.D., Assistant to Professor of Materia Medica, Edinburgh; H. Aubrey Husband, M.B., Lecturer on Medical Jurisprudence in the Extra-Mural Medical School, Edinburgh; Francis Ogston, jun., M.D., Aberdeen; W. J. Simpson, M.D., Aberdeen; and John Urquhart, M.D., Aberdeen—of whom Dr. Matthew Hay was elected to the vacant post. This gentleman was educated at the Universities of Glasgow and Edinburgh. At the latter University, in 1878, he graduated as Bachelor of Medicine and Master in Surgery with first-class honours, obtaining also the Ettles prize for the most distinguished graduation in medicine of that year. In the same year he was appointed Demonstrator of Practical Materia Medica and Assistant to the Professor of Materia Medica in Edinburgh University. After filling the office of Assistant Physician to the Edinburgh Royal Infirmary, he was in 1880 appointed Physician to the New Town Dispensary. In the following year he graduated as Doctor of Medicine, carrying off the gold medal as well as the Goodsir prize. Dr. Hay carried off two months ago the sanitary research scholarship (open to all British graduates in medicine) offered by the Grocers' Company of London. The fact that an outsider who has made no special study of the subject he has to teach has been elected will be keenly felt by the local candidates. The Court has in effect stated that the University cannot produce men good enough to be professors. With but few exceptions all the professors are Edinburgh men.

PUBLIC WASH-HOUSES FOR EDINBURGH.—At a meeting of the Town Council of Edinburgh, held last week, the Lord Provost's Committee recommended the acquisition of a site for wash-houses, and the erection thereon of public wash-houses, at a probable cost of £1,500, and of twelve baths, at an additional cost of £250. It will be recollected that in a recent number we called attention to the absence of public baths in Edinburgh. We congratulate the Town Council on the prompt action they have taken on our remarks.

THE SCOTCH UNIVERSITIES BILL.—At a meeting of the University Court of Aberdeen, held on the 28th ult., Mr. Webster, M.P., who was present as the Lord Rector's Assessor, made a statement, on the invitation of the Lord Rector, with regard to the Universities Bill. Mr. Webster said the Bill would assuredly make its appearance again, probably more or less modified, and it was certainly susceptible of great improvement. The chief ground of objection hitherto taken was as to the power proposed to be given to the contemplated University Commission. He deprecated the extreme hostility to the proposal expressed by the University of Glasgow, and scouted the alarms indulged in by that University. He would certainly prefer a well-selected Commission, dealing with University reform, as proposed by the Bill, than the proposal of Mr. Dalrymple, M.P., who had given notice to move that it was desirable that the constitutions under which the Universities were to act in future, instead of being left to an Executive Commission to alter or revise, should be laid down in Parliament and included in the Bill. He (Mr. Webster) thought that the House of Commons, especially in Committee, was exceedingly unfit to deal with all the details and niceties of Scotch academical constitution, and he thought the proposed Commission was preferable subject to such checks and securities as ought to be applied more strongly than at present, and subject also to a simpler and less expensive form of appeal than the Bill provided. A Commission so constituted would not be apt to abuse its powers or run into dangerous courses, as Glasgow University fancied. He, however, was not indisposed to hold that the revision of "constitutions" should be withdrawn from the powers of the Commission; and he thought it probable that the Government would so modify these powers in view of the representations that had been made. The second chief ground of objection was as to the financial proposals. On these Mr. Webster dwelt at some length, saying that the financial clauses of the Bill must be withdrawn or modified to a very great extent, otherwise the Bill would be undeserving of support.

THE SANITARY INSTITUTE OF GREAT BRITAIN.—The programme of the arrangements which have been made for the autumn Congress of this Institute, which is to be held in Glasgow on the 25th inst. and following days, under the presidentship of Professor G. M. Humphry, has been issued. The Congress will sit in three sections—Section 1, "Sanitary Science and Preventive Medicine," being presided over by Professor W. T. Gairdner; section 2, "Engineering and Architecture," by Professor T. Roger Smith; and section 3, "Chemistry, Meteorology, and Geology," by Professor R. Angus Smith. A reception-room will be opened on 24th September at the St. Andrew's Halls, where also will be held the sectional and general meetings of the Congress. The proceedings will commence on Tuesday, 25th September, with a public luncheon, after which an exhibition of sanitary appliances, &c., will be opened in the Burnbank Drill Hall by Lord Provost Ure. The first general meeting will be held in the evening, when the opening address will be delivered by Professor Humphry. A *conversazione* is to be given in the Corporation Galleries on Wednesday evening, and on Thursday evening there will be a lecture by Dr. B. W. Richardson. The closing general meeting of the Congress will take place on Friday afternoon, a public dinner being fixed for the evening of that day, and on Saturday evening an address to the working classes will be delivered by Dr. Alfred Carpenter, of Croydon.

Correspondence.

HYDROPHOBIA 450 DAYS AFTER THE BITE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—On the 11th inst. I was sent for to see Wm. Fogarty, a well-made, wiry, previously healthy labourer, about 36 years of age, married, of buoyant spirits, but excitable, particularly when under the influence of drink, which used to be often, but lately seldom. On the 9th inst. he went to work in his usual health and spirits, was engaged thatching a hayrick and other work about hay in a cool, airy situation of between 800 and 1,000 feet elevation. The day was cool and showery (I am particular in these details in order that you may judge of the possibility or probability of the sun causing the attack). Towards noon he felt a langour and "heaviness" unusual to him. He worked on, however, and took his dinner at the usual time. Afterwards the "heaviness increased, with giddiness," his "head reeling" (his own expressions are in inverted commas), and "everything around" him "began to appear red, changing gradually darker, till at last even the trees looked nearly black." He left off work at the usual hour, between 6 and 7 o'clock; did not go to the farmhouse for his supper as usual, but went home; felt very thirsty, went several times to a spring near his house, and drank copiously; went to bed early, got a "shivering fit" and "a terrible pain in front and top" of his head. Still very thirsty, and drank a great deal of whey. "Headache abated after about two hours," and he "fell asleep," but awoke in about two hours afterwards. Still very thirsty. Asked his wife for something to drink, but when he put it to his lips and attempted to swallow, "a spasm took" him, "beginning at the pit of the stomach," and "going up" to his "throat and jaws," making him "gasp for breath." Each time he tried to drink, "the same spasm shook" him, but by perseverance he managed to swallow some, but at length gave up attempting, as he found it weakened him. He became very restless and uneasy, and did not sleep again. This condition remained unaltered all day Friday, 10th inst. On Saturday, 11th inst., sent for me. I saw him at 12.30 p.m.; found him in bed, half sitting, half reclining; pale, anxious, and frightened-looking; a profuse perspiration on his head and face; his voice nervous, jerky, and hoarse; his skin felt cool (had not my thermometer on that occasion); pulse 78, full and regular; tongue moist and clean; throat and fauces natural; pupil unaltered, *heart's action normal*—in fact, no *abnormality* except in his aspect and voice; no thirst, no headache, no uneasiness except mental disquietude and a feeling of great weariness, until he tried to drink, when he was at once seized with a convulsive spasm and gasping for breath. The mode of attack requires description. On being handed the cup, he trembled perceptibly, looked at it for a moment as if trying to make up his mind whether he would attempt to drink it or not, raised it with a sudden, jerky motion to his lips, *tossed* off one mouthful, which he gulped down rather than swallowed, gasped for breath once or twice, and threw himself back upon the pillow apparently exhausted. He told me that if he did not do it in that quick way he "would have no chance at all of swallowing any," and his wife told me that he made very much better attempts then than he had made at first. I watched him closely during the attempts to drink, and saw that the diaphragm acted largely in producing the spasmodic attack of difficulty of swallowing and breathing, but not solely, as all the muscles of deglutition and respiration seemed engaged, and his whole frame would shake on first taking the vessel in his hand. I induced him against his will to try a little solid food, which he had not done for forty-eight hours before. He chewed a morsel of bread, and swallowed it without much apparent effort, but could not be induced to try another. After allaying his anxiety as well as I could, I left him, and returned at 8 p.m. He could then swallow a little better; but whilst examining him I found that the slightest contact of my hands, which were cold, produced a convulsive gasping for breath. The air from an open window near, to which he turned to allow me to see his throat, had the same effect. I got him to swallow some good broth as concentrated as we could have it in so short a time; gave him a third of a grain of morph. mur. At his request, his wife gave him his pipe lighted, but he was not able to take more than a few whiffs on account of the spasmodic gasping caused by each attempt to "draw" it. He slept a little that night; had not slept before for over forty-eight hours, and awoke very much refreshed. Saw him again on 12th, at 10 a.m. Aspect much improved, speech normal, tongue slightly furred, fauces dry, not more than might be due to the dose of morphia; skin normally moist, pupil unaltered; secretions apparently natural, but did not test the urine; pulse 90, of fair rhythm and fulness; temp. 96·6; no headache nor pain anywhere, and no other uneasiness than a feeling of great weariness and weakness, until he tried to swallow, when he experienced the same effects as described above, but rather less intense.

13th, 10.30 a.m.—Found him restless and wandering; distinct mental disturbance; perverted smell and taste—the former gave him great trouble, as he could not lie in bed "on account of the smell." I could not perceive any unusual or disagreeable odour. During the night was allowed to go out in the wet and cold, which must have acted very injuriously. Hyperæsthesia increased. Found him standing outside his house, and every breeze of air that fanned his face caused him to gasp spasmodically, yet he would not go in on account of the bad smell. His wife and a man assisting her were unable to restrain him or persuade him to lie down, but he did so for me. I found the temp. 100·4, pulse 90; hands cold, which I attribute to exposure; great aversion to try to swallow anything, and is greatly irritated if asked to do so; continually "hawking" up mucus out of the throat, but only in very small quantities; *saliva not increased*, and the throat looks dry and glazed, as if *varnished* inside, with here and there a little adherent frothy-looking mucus. Removed him to his father's house, well protected from cold, &c.; got him to swallow a little warm milk, and gave him a third of a grain of muriate of morphia; slept a little through the day. Was apparently better at 9 p.m., but complained of a "numbness," which he told me of in the morning, in the hands and arms, especially the left, increasing so that he cannot now raise his hand to his mouth except with difficulty, on account of this benumbed, paralysed condition. Temp. now 101·6, pulse 86, less full than it has been; pupil *dilated;* hyperæsthesia apparently rather less; contact of my hand does not affect him; throat again normal-looking; gave him another third of a grain of morphia and some warm milk, in which he took a little bread.

14th, 10.30 a.m.—Found him restless and wild-looking; appearance that of a maniac, impatient of control, and when restrained from going out, which he has tried to do through the night and morning, becomes excited, and would be violent but that his arms are now so paralysed that he cannot raise them, though he still has the power of using his fingers and hands; cannot tolerate his father near him, and seems suspicious of every one, and they all seem afraid of him, and will not attempt the least restraint, so that he has been allowed to expose himself to cold, and undergo exertion during the night and morning, which must have acted very injuriously, consequently I was obliged very reluctantly at this late stage of his malady—and they would not hear of it before—to have him removed to Callan Workhouse Hospital. I laid him down as carefully as possible in my own trap, and accompanied him myself. I left him pretty comfortably settled in bed at 3 p.m., in charge of Dr. Walsh, of Callan, who has kindly given me the following additional details:—He took some beef-tea in the evening; was quiet and seemingly at ease at 10 p.m. (14th); slept a little; awoke in violent delirium, which gradually exhausted itself; he vomited a quantity of green viscid matter, became semi-comatose, and died quietly at 8 a.m. on 15th inst. A post-mortem could not be procured, but decomposition set in very rapidly.

On 18th May, 1882, four hundred and forty-eight days before the first symptoms of his fatal malady began, he was bitten by a dog which showed symptoms of rabies (the constable R.I.C. who destroyed the dog a short time after the occurrence asserts that it was a well-marked and undoubted case of rabies). This dog, a strange one, strayed into a house in the village of Kilmogany and lay under a form. Fogarty stooped to coax the animal, when it bit his nose, transfixing the fleshy portion of the septum with one tooth, and penetrating and scratching the left ala with another. In about three and a-half hours after receiving the bite he applied to me. I passed a red-hot iron wire repeatedly through the wound in septum, and also cauterised well the other wound. He bore the operation without flinching, and it seemed to relieve him of some anxiety, thinking it was a preventive against any future ill-effects. The wound healed rapidly, leaving very slight cicatrices.

The great interest you have taken, and the valuable information you have given in the *Medical Press* about hydrophobia, encourage me to ask you for space for this report of a case which, to me, seems to possess many points of peculiarity and interest, in hopes of eliciting some comments from those who have had an opportunity of studying similar cases. I beg to apologise for its length, and to remain

Yours faithfully,
Walter May.

Kilmogany, Callan.

◆

THE TREATMENT OF CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In view of the possible invasion of cholera to our shores allow me to trespass on your valuable space, with a few brief notes of an experience of the epidemics of 1867-8, gained while assistant medical officer resident, in British Hospital, Buenos Ayres, South America.

Firemen and stokers from steamers coming from infected port, London, the London Dock being especially bad, were in each epidemic our first cases; impressing with the fact previously noted, with regard to yellow fever when in Demerara, viz., the effect of change of climate producing a state of constitution susceptible to the influence of a latent poison, which not only acts on an individual, *but is capable of being disseminated by him.*

The following measures obtained during first and early part of second outbreak under the constant supervision of Dr. R. Reid and assistants:—

Rubini's and other spirits, camphor, chlorodyne all kinds, astringent and carminative mixtures, calomel and quinine, chlorate of potassium, inhalation of chloroform, lead and opium pills, aromatic sulphuric acid, viz., opii and "black drop," brandy and wines separately and combined, spinal ice bags, hot jars, sand bags, sinapisms, liniments.

The results obtained from this line of treatment was most disappointing not only in ours, but also in the Irish, Italian, German, and Spanish hospitals, more than one conference having been held on the subject by the various physicians.

About the second week of the second outbreak, we got a suggestion from Dr. Nelson, one of the Canadian commissioners, acting on which we adopted the following line of treatment with marked success:—

The patient on first complaint of a sense of general uneasiness was put to bed and lightly, *very lightly*, covered. The thorough ventilation of the room attended to. When vomiting and diarrhœa of the unmistakeable character occurred they were encouraged by copious draughts of cold water till the stomach appeared quite clear of all food. The stomach and intestines being emptied every effort was directed to stilling the irritable organ and subduing the restlessness of the patient.

To this end a pill one grain of fresh opium from centre of large lump, we administered dry. A physician or assistant sat at the bedside till it took effect, promising patient, in response to his unfortunate cry of "water, water," that if he did not sleep in a few minutes he should get some, the reason for this being that, if the stomach contains any food it will be, with the water and the pill, again ejected, in which case cold water was again given to clear the stomach, and if the pill returned another was administered, absolute rest and quiet enjoined, and, as life or death depended on the next few hours' results, every attention was concentrated on them.

Sleep usually occurred and lasted from 10 to 15 minutes, when the patient woke with the cry for "water, water," which was satisfied by a tablespoonful of acidulated water.

℞ Acid tartaric, ʒss;
Aqua, ℥x. M.

which was given every time patient woke or was restless.

All dejections were disinfected with solution of carbolic acid and immediately removed, bed pan with disinfectant found essential.

No food was given for four, five, or six hours, and then very cautiously and fluid, and not until the patient becomes decidedly improved, and the natural functions of the system restored.

(The meddling kindness of friends of patients lost us several cases, from disregard of this; a few tablespoonsful of arrowroot with a little port wine in it has caused death in a few minutes, in some whose convalescence was rapid and well assured, and hence instructions were always impressive on this point.)

Having thus conserved the strength by rest, and tended to restore the waste caused by the transudation of the serum of the blood and the tissues, by the gentle sponging of the arms, hands, face, and legs with tepid water; a process most grateful to the patient, convalescence becomes marvellously rapid, and the diet may be more liberal, and next day was aided by the addition of a little port or other wine.

Being so circumstanced that the part of nurse as well as physician had to be taken by the medical staff, the attendance in each case was without intermission, while it was in the few hours struggle out of which patients usually emerged for life or death.

Some 230 cases came thus under our care inside and out of hospital, and we were led by this experience to the following important conclusions, viz.:—

1. That in Asiatic cholera, during onset and prevalence of severe action of the poison, all stimulants and medical draughts are worse than useless and only tend to increase the irritability of the stomach, and waste the strength of the patient by increasing the diarrhœa and vomiting.

2. That a free current of air, which was always sought for by the patient, was most beneficial to him, while hot jars, sand in bags, sinapisms, and counter irritants only add to the indescribable torture which already afflicts him.

3. No emetic is needed but *cold* water.

4. That perfect rest of body is, in the majority of cases, sufficient to prevent cramps, or at least to mitigate the severity of them.

5. That when a physician is called to the patient who is in a state of collapse or rather profoundly under the influence of the presence of the poison, for some hours or even less in severe cases, when the breath is colder than the surrounding atmosphere, when all secretion has ceased, and the pulse cannot be felt either at elbow or axilla, and circulation having practically ceased, while the heart meantime continues to beat, and the mind remains sometimes preternaturally clear, it is useless, if not actually cruel, to apply treatment more active than tepid or cold affusion externally, with a tablespoonful of some acidulated drink as above, every ten minutes or quarter of an hour.

The typhoid stage, so called, when reached by patient, gave least hope to the physician, as none lived beyond the tenth day, and those cases were very few, as most succumbed at or before the fifth day.

The importance of the subject will I trust justify my trespassing at such length.

I am, &c.
S. M. Thompson,
Res. Physician, South Union, Dublin.

◆

FEES FOR MEDICAL EVIDENCE AT WORKHOUSE INQUESTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A medical friend has called my attention to an article in the issue of the *Medical Press* of the 25th of July last, headed "Fees for Post-mortem Examinations," which both he and I consider of some practical importance to the profession, and ought not to be allowed to rest in abeyance. As the coroner engaged on the case in question, it may be assumed that I am perfectly cognisant of all the facts, and hence I say the grand jury had no right to disallow the medical fee, nor the judge, with all due respect for his high authority, to summarily dismiss the presentment for it, and thereby approve the action of the grand jury. No question arises with respect to the grand jury itself, which is composed of an excellent body of honourable men; but their sub-committee took a mistaken view of their privileges and powers, and so reported to the grand jury, who in turn took all for granted, and so perpetuated the blunder. I put aside the misleading, narrow special pleading put into the mouth of the chief secretary, where he is made to say the grand jury, "after careful investigation, disallowed medical fees *recommended* by the coroner and amounting to five guineas." The coroner made *no such recommendation.* He simply submitted to the committee a claim put in by a solicitor for fees for two medical gentlemen called in at the instance of another medical gentleman who thought himself aggrieved about a midwifery case, but in the same breath said he did not approve or disapprove of payment to them, inasmuch as he himself had "summoned and ordered" three eminent medical men, who attended and gave most lucid and satisfactory evidence to the jury quite sufficient to meet all the requirements of justice and of the law. So much for *four guineas;* but the one guinea which he persistently claimed for the M.D. evidence given in the Granard Union workhouse was a most legitimate fee. No dispute or controversy in the most remote degree took place in the committee-room, but two of the members of committee seemed to think that because the inquest was held in a workhouse the coroner *was bound* to accept the evidence of the workhouse doctor, who, according to their lights, should submit himself for examination without a fee. On this erroneous assumption two at least of the committee acted, while I felt that our chairman stood in a minority on the point, for he actually told me he would be quite satisfied to see the ruling then made revised. With regard to the law of the case, there appears to be very little mystification about it. Sec. 32 of 9 & 10 Vic., c. 37, sets people a-thinking that a workhouse medical officer is *not* to be paid a fee for skilled evidence given in the house over which he presides as the supreme arbiter of life and death. He is to enlighten the jury free gratis for nothing. But that section of the Act has reference only to any public hospital or infirmary, or to any building or place belonging thereto or used for the reception of the patients thereof, or any county or other lunatic asylum, or any public infirmary, or other public medical institution, whether the same be supported by endowments or by voluntary subscriptions *et cetera.* Not a word in the Act about the Granard Union Workhouse. I am happy to be able to say His Excellency is likely to set at rest very soon all cavil about calling in medical witnesses in every public institution in this country. Through the courtesy of his assistant secretary, Mr. W. S. B. Kaye, I am informed that a circular dated 9th April, 1883, has been addressed to "The Resident Medical Superintendent" of lunatic asylums and others referred to in the foregoing sec. 32, informing them that "they should inform the coroner, should the coroner request them to hold a post-mortem examination, that the Government consider it undesirable that they should act on such occasions." The circular is emphasised by the additional notification, "Please acknowledge the receipt of this circular," and that the question of issuing a similar circular in the case of prisons and workhouses is now under consideration. It would be in some degree a hardship to exclude medical officers in *all cases* from giving evidence. Of course, in the case of lunatic asylums and kindred institutions, the medical officer in charge may care little for the effect of the circular on him, being faithful to his duties, for it is not proposed at present to alter the law which so unmercifully precludes him from a fee, but a workhouse or prison medical superintendent has an absolute and legal claim to his fee, if called on by the coroner in cases which occur within his own charge. So far as the circular of April, 1883, goes, it is a step in the right direction. The medical superintendent of the institution under notice should no doubt inform the coroner that on the highest authority which he can recognise, he is not an eligible person to hold a "post mortem" examination in a similar case—the coroner should be equally made aware that such evidence is not eligible; this solely applies to *post-mortem* cases; but how many cases occur in which it is not deemed necessary to hold a post-mortem at all, and yet death from culpable negligence may be proved from external evidence. It may be that the cause of death is wrapped up in mystery, and yet not the slightest stain of reproach laid at the door of the medical superintendent. Why, then, not admit him to evidence, and let him have his fee? Surely coroners and jurors can be entrusted to take care of false coin and counterfeit testimony. Generally the coroner and his jury know their men, and will give them credit for all they are worth, and if necessary summarily set them aside. These remarks apply equally to lunatic asylums and others of that class, equally with workhouse and prison doctors. The misfortune of the moment is that inconsiderate rulings like that of Judge Lawson at Longford make men's hair stand erect to know what is and what is not the law of the land.

I am, &c.,

Longford. M. FULLAM.

◆

DR. CAMERON, of Dublin, is at present engaged in the analysis of some meat sent from New Ross, through eating portions of which some harvest labourers died on Saturday. It was at first supposed that the heifer had been previously bitten by a rabid dog, but later suspicions point to deliberate poisoning.

University of London.—The following are Lists of the Candidates who have passed the recent Honours Examinations:

EXAMINATIONS IN MEDICINE:—ANATOMY.

First Class.

Thane, Edgar Herbert (Exhibition and Gold Medal.)
Johnson, R. (Gold Medal.)
Washbourn, John Wychenford.

Second Class.

{ Goodall, Edward Wilberforce.
{ Hart-Smith, Franke C.
Wild, Robert Briggs.
Gray, John Power William.
Halstead, George E., B.A., B.Sc.
Wills, William Alfred.

Third Class.

Davenport, Arthur Frederick.
Jones, Sydney Harold.

MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

First Class.

Johnson, Raymond (Exhibition and Gold Medal.)
* Thane, Edgar Herbert.
{ * Calvert, James, B.A.
{ * Carless, Albert.
{ * Corbin, Eustace R. St. Clair.
{ Finley, Frederick Gault.
{ Gardner, Henry Willoughby.
{ Gow, William John.
{ Stevenson, George.

{ Braddon, William Leonard.
{ Davenport, Arthur Frederick.
{ Wild, Robert Briggs.
{ Wills, William Alfred.

Second Class.

{ Hichens, Frank.
{ Leech, Priestley.
{ Muspratt, Charles Drummond.
{ Washbourn, John Wychenford.
Childe, Letterstedt Frederick.

Third Class.

Stedman, Frederick Osmund.
{ Barendt, Frank Hugh.
{ Lever, Frederick.

ORGANIC CHEMISTRY.

First Class.

Washbourn, John W. (Exhibition and Gold Medal.)
{ † Hichens, Frank.
{ † Stevenson, George.

Second Class.

Halstead, George Ezra.
Braddon, William Leonard.

PHYSIOLOGY AND HISTOLOGY.

First Class.

Wild, Robert Briggs (Exhibition and Gold Medal.)
Thane, Edgar Herbert (Gold Medal.)

Second Class.

Bright, Eustace Frederick.
Finley, Frederick Gault.
Braddon, William Leonard.
Gow, William John.
Johnson, Raymond.
Leech, Priestley.

Third Class.

Lever, Frederick.
O'Brien, Patrick Moriarty.
Edge, Frederick.

PRELIMINARY SCIENTIFIC EXAMINATIONS (M.B.):—INORGANIC CHEMISTRY.

First Class.

Starling, Ernest H. (Exhibition.)
* Hatch, Frederick Henry.
Bloxam, William Popplewell.
Roberts, John Lloyd.

Second Class.

Sutherland, G. W., B.A. Syd.
Jones, Hugh Richard.
Overbeck, Otto C., J.G.L.

Third Class.

{ Ashworth, Percy.
{ Black, George.
{ Taylor, Frederick Howard.
{ Ashe, Evelyn Oliver.
{ Cooke, Cecil Whitehall.
{ Rennie, George E., B.A. Syd.
Harris, Walter. Field, Alfred Ernest. Hensley, Philip Henry.

EXPERIMENTAL PHYSICS.

First Class.

Buchanan, J. (disqualified by age for the Arnott Exhibition and Medal.)
Starling, Ernest Henry.

Second Class.

Roberts, John Lloyd.
Baker, Edward George.

Third Class.

Finnegan, John Maxwell.
{ Adamson, Mary Madeline.
{ Chambers, Jesse Mary.
Jones, Hugh Richard.
Ashworth, Percy.
Whitehead, Henry Edward.

BOTANY.

First Class.

Boyce, Rubert William (Exhibition.)
* Starling, Ernest Henry.
Fernau, Charles Hermann.

Second Class.

Powell, Llewellyn William.
Blake, James Edward Huxley.
Gardiner, John.
Baker, Edward George.

Third Class.

Hastings, Edwin Birchall.

ZOOLOGY.

First Class.

Rennie, George Edward.
Fernau, Charles Hermann.

Second Class.

Brindley, Albert Edward.
Gardiner, John.

Third Class.

{ Durham, Arthur Ellis
{ Wood, Frank Lomax.

* Obtained the number of Marks qualifying for the Exhibition and Medal.

† Obtained the number of Marks qualifying for a Medal.

N.B.—The bracket denotes equality of merit.

Notices to Correspondents.

The Students' Number, 1883-84.—The annual educational number of this Journal will be published on Wednesday, September 19th. Deans, Registrars, and others connected with the various medical schools throughout the United Kingdom, will oblige by forwarding the latest prospectus and such other information as will assist the Editors in the compilation of this important number.

OPERATIONS ON PAUPERS.

Aliquis asks what course should be followed under the following circumstances: A patient is admitted for treatment into a workhouse hospital, or is being attended at his own home on a relief ticket. He has, say, extensive disease of the bones of the foot, and amputation or some other operation is considered necessary by the medical officer. 1. The patient himself objects. 2. The patient is willing, but the near friends object. Is the medical man to persist in operating?

[The surgeon must on no account operate without the consent of the patient, or, if a child, of those who are responsible for his care. The opinion of friends and relations go for nothing. If the patient refuses, care should be taken to throw upon him the whole responsibility of death or injury sustained thereby.—Ed.]

The Treatment of Comedones.—A correspondent, in reply to the letter signed "An Old Reader" in our last, asking advice on the treatment of "Comedones," suggests the employment of Haseline, with which he has had some success.

Mr. Urquhart (Edinburgh).—It is not usual to give the names of anonymous writers. In the present instance your telegram has been forwarded to the writer, who will perhaps communicate with you.

SCARLET RUNNERS.

To the Editor of the Medical Press and Circular.

Sir,—In reply to your correspondent "Staphyloma's" second query in your last issue, you say: "It is contrary to the regulations, and a ticket *filled up* by another person than the Committeeman or Warden may be disregarded." The italics are mine. Do you adhere to that statement in the following case of everyday occurrence to myself? The Committeeman *signs* the entire book of tickets *en bloc:* the applicant calls for a ticket, the clerk to the Committeeman fills up the body of it, and the ticket is presented to me *duly signed* by a member of my Committee. I want to know, would I be justified in "*disregarding*" that ticket, and would the Local Government Board *approve* of my so disregarding it?

Yours very truly,

Hard Worked.

[A ticket so filled up is undoubtedly invalid, and might be disregarded without leaving the medical officer open to any charge of breach of rule or neglect of duty. The 9th section of the Medical Charities Act declares that the Committeeman or Warden, and no one else, may direct the medical officer to afford advice and medicine by "a ticket in such form as the Commissioners may prescribe, addressed to the medical officer." Under this authority the Commissioners did prescribe a form, and declared by article 31 of the Regulations (page 243, Irish Medical Directory) that "the ticket and counterpart are both to be *filled up* by the person authorised to issue the ticket," and "care should be taken in the issue of the tickets accordingly." Some years past one of the medical officers of a South Dublin Dispensary appealed to the Local Government Board against the systematic issue of tickets, by a pot-boy on behalf of his master, a Committeeman. The reply of the Local Government Board did not order attendance on such tickets, but simply recommended it in suitable cases, and made it clear that such tickets were and are legally invalid. The best course, we think, would be for the medical officer to attend at first on the ticket, lest the patient might suffer injury, but to refuse to attend a second time until a properly filled ticket is presented. But, if he attend, it is entirely a matter of expediency, not of law.—Ed.]

A Nervous Traveller.—The phenomenon which occurs to you when travelling is no evidence of faulty vision, but is common to most persons when travelling rapidly by railway. The better plan is to shut, or turn your eyes from near objects, such as passing trains; open scenery and distant objects need not be avoided, as they while away the tedium of travelling, and are in no sense hurtful even to so nervous a traveller as you.

L.R.C.P.—In a recent ramble through North Devon, we visited the hotel ourselves, and are satisfied that the reports as to its insanitary condition have no foundation in fact. We met several members of the profession during our stay there, and all agreed that since the new system of ventilation and drainage had been in force, the "Ilfracombe" was as near perfection as a hotel could reasonably be.

Mr. Hardy.—Taking refraction into account, the angles of depression would be all reduced by about one-sixteenth if you repeat the experiment on obverse lines.

Neuralgia.—Croton-chloral gives relief in neuralgia, especially in its chronic forms, by producing anæsthesia of the sensory portions of the fifth (facial) nerve. This relief, however, is only temporary, and must be employed as a means of gaining time for other treatment. We have not obtained good results from sodium salicylate. Dr. Martin's case appears to us to be simply one of enteric fever with blocking up of the cæcum by unhealthy fæcal matter. It is evident, moreover, that this enteric fever was brought on by one of its most frequent causes, viz., sewage gas. We are quite aware of the present fashion in medicine to attribute almost every disease under the sun to either chronic syphilis or suppressed gout; but allowing for this, and admitting that Dr. Martin's patient may have gone in the way and contracted every form of venereal disease, we do not think that syphilis had anything to do with the illness so admirably managed and reported by Dr. Martin.

Dr. Johnson (Kilkenny).—We have forwarded your note to the writer of the article, and hope to give you an answer in our next.

Mr. J. H. Evans.—Thanks; each department is at present filled.

A New Synonym for Quinine.—At Croton, New York, common drugs are sold at all the stores. Recently an Irishwoman entered one of them, and said to a new clerk: "Would ye be afther putting up for me a pound of Queen Anne's powders?" The clerk took down a package of Royal baking powder and was doing it up, when she exclaimed—"Not that at all; me Pathrick is sick wid the African faver." "The what fever?" inquired the clerk. "The nigger faver," replied the woman. "An ye should see poor Pathrick shake. He hasn't a tooth left." The woman got the quinine which she wanted.—*Gaillard's Med. Jnl.*

Vacancies.

Castlebar Union, Castlebar Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, September 8.
Central London Ophthalmic Hospital.—Assistant Surgeon. Applications to the Secretary on or before September 11.
Dursley Union.—Medical Officer. Salary, £80. Applications to the Clerk to the Guardians before September 12.
Hospital for Women, Soho Square.—House Physician. Applications to the Secretary on or before September 20.
Leeds General Infirmary.—House Physician. Salary, £100, with board, &c. Applications to Dr. Clifford Allbutt on or before September 12.
Sheffield.—Medical Officer of Health. Salary, £500. Applications to the Chairman of the Health Committee before September 6.
St. Bartholomew's Hospital.—Assistant Physician. Applications to the Clerk before September 11.
St. George's Union, Middlesex.—Assistant Medical Officer. Salary, £120, with furnished apartments and rations. Applications to the Clerk to the Guardians before September 10.
St. Peter's Hospital for Stone and Urinary Diseases.—House Surgeon. Honorarium, 25 guineas, with board, &c. Applications to the Secretary on or before September 25.
Western General Dispensary, Marylebone Road.—Honorary Physician. Applications to the Secretary before September 10.
West London Hospital, Hammersmith.—Assistant Physician. Applications to the Secretary on September 24.

Appointments.

Cooper, A. N., L.R.C.S.I., Demonstrator of Anatomy in the School of Surgery, Ireland.
Fox, T. C., M.B. Lond., M.R.C.P.L., Physician to the Skin Department at the Westminster Hospital.
Hart, H. W., M.R.C.S., L.S.A. Lond., House Surgeon to the Hartlepools' Hospital.
Loveridge, A. W., M.R.C.S., L.S.A. Lond., House Surgeon to the Clayton Hospital and Wakefield General Dispensary.
Lyttleton, W. M., M.D., L.R.C.P. Ed., M.R.C.S., Government Medical Officer and Vaccinator for the District of Adelong, New South Wales.
Newell, F. T. P., Resident Medical Officer to the Meath Hospital.
Park, R., M.D. Glas., Assistant Resident Medical Officer for the Riccartsbar Asylum.
Richmond, J., M.B. Oxon., M.R.C.S., Assistant Medical Officer to the Crumpsall Workhouse, Manchester Township.
Robinson, J. W., M.D. St. And., M.R.C.S., L.S.A. Lond., Honorary District Surgeon to the Royal South London Dispensary.
Shaw, J., M.R.C.S., Government Medical Officer and Vaccinator for the District of Manning River, New South Wales.
Trimble, J. M., M.D., M.S.Q.U.I., Medical Officer for the Strabane Dispensary District.
Wilson, G. B., L.R.C.P. Ed., L.R.C.S. Ed., Second Assistant to the Resident Medical Superintendent of the District Lunatic Asylum, Cork.
Winder, W. H., L.R.C.P.L., M.R.C.S., Resident Assistant Medical Officer to the Crumpsall Workhouse, Manchester Township.

Births.

Cockell.—August 26, at Richmond Road, Dalston, the wife of Fredk. E. Cockell, jun., M.R.C.S., of a son.
Martin.—August 21, at Arnheim, Blackburn, the wife of John M. H. Martin, M.D., of a son.
Rae.—August 23, at Duckspool House, co. Waterford, the wife of William Masters Rae, of a daughter.
Smith.—August 25, at Beech Lodge, Kinnetty, the wife of Thomas Orde Smith, M.B., T.C.D., of a son.
Webb.—August 26, at 4 Wymering Terrace, Lavender Hill, S.W., the wife of Hy. Pelham Webb, M.B., of a son.
Wright.—August 29, at 49 Talbot Street, Southport, the wife of S. H. Wright, M.D., of a son.
Wynn-Williams.—August 19, at Penywern, Brixton Hill, the wife of T. Wynn-Williams, M.R.C.S., of a daughter.

Deaths.

Anderson.—August 30, at Pitlochrie, N.B., Margaret, wife of Arthur Anderson, M.D., C.B., Inspector-General of Hospitals.
Bartleet.—August 25, at Ladbroke Gardens, Notting Hill, Joseph James Henry Bartleet, L.R.C.P., &c., aged 43.
Highmore.—August 28, at Sherborne, Dorset, William Highmore, M.D., aged 67.
Smith.—August 24, at Morningside, John Alex. Smith, M.D. Ed.
White.—August 27, at The Orchard, Penzance, Wm. Todd White, F.R.C.S., late of Hammersmith, aged 64.
Willings.—August 23, at The Limes, Waterloo, Hants, Richard Willings, M.R.C.S., aged 71.

ON OCCLUSION OF THE POSTERIOR NARES AS A RESULT OF NASAL CATARRH.

By ALEXANDER W. MACCOY. M.D.,
Philadelphia.

So much has already been written during the past few years concerning the pathology and treatment of chronic nasal catarrh, that it is with no little hesitancy I offer my contribution to its study.

I should scarcely have an apology for offering this paper, were I less convinced that a new era had arrived in the successful management of what was, and, by some, is yet considered an incurable disease. The spirit of incredulity has so completely possessed the minds of many, that any one professing to cure chronic nasal catarrh runs the risk of being considered an enthusiast.

In our humid and variable climate, affections of the nasal mucous membrane are all but universal. In some cases of nasal catarrh, but little appreciable ill-effect results; in others, the progress is steadily onward from year to year, to one certain end—nasal occlusion, partial or complete. Between the beginning and the result, in these latter cases, there is a period of discharge of muco-purulent or serous secretion, which increases with each acute exacerbation during the winter and spring, but lessens considerably during the summer, and in some cases is almost absent.

The course of chronic nasal catarrh of the *hypertrophic* variety (of which variety alone I wish to speak in this paper) is undoubtedly of long duration, extending over many years, and in many persons appears to have been the companion of their lives.

After considerable observation, I am of the opinion that no hypertrophic condition of the nasal mucous tract arises in any case except from a long-continued and persistent coryza. Hypertrophic change cannot be present without previous inflammation: the hypertrophic tissue is the *result* of the persistent irritation—the *effect* of an ever-active *cause*.

Only during the last few years has the rapid development taken place in our knowledge of diseases of the nasal cavities.

To native investigators we are indebted for much of the advance in pathology and treatment, and, as a clearer understanding of the true anatomy of the parts has obtained, the pathology has become so clearly established, that the mind has no alternative but to accept it.

The *peculiar* anatomical characteristics present in the mucous membrane lining certain portions of the nasal cavities, were prominently pointed out by Kölliker and by Kohlrausch twenty nine years ago, who described, in the sub-mucous layer, what they termed venous channels, great in size and very numerous—out of all proportion to what were known to exist in other mucous tissue. Kohlrausch's discovery was not attended by any practical results, because this anatomical knowledge was far in advance of his time, particularly as to its bearing upon nasal catarrh.

Twenty years after Kohlrausch had made his observations, Dr. Bigelow, of Boston, made a much more elaborate and successful study of this peculiar anatomy. While Dr. Bigelow's observations confirmed those of Kohlrausch, as to the enormous venous channels in the sub-mucous layer of the nasal cavities, he also proved that these sinuses constituted a true erectile tissue, such as is most clearly observed in the corpora cavernosa, capable of dilation and contraction.

Bigelow's investigations have been repeatedly confirmed by observers in recent years. To these later observations are we indebted for refreshing our memory concerning this unique structure, and most of all, concerning the practical bearing which this information has had in building up so clear a pathology.

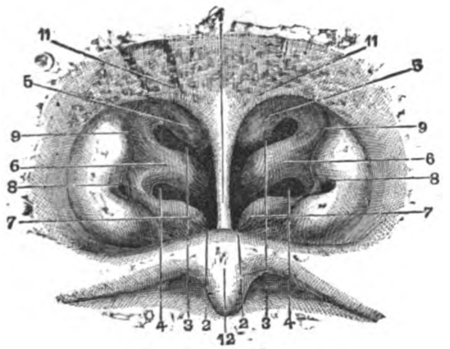
If, then, we keep a clear understanding of the anatomy of the mucous membrane lining the nasal cavities, the conditions found in hypertrophic disease are readily understood.

In examining cases of long-standing nasal catarrh, we are almost certain to find hypertrophic changes most clearly defined in those portions where the erectile tissue is most abundant—over the turbinated bones and the vomer.

It is my purpose to limit these observations to that portion of the nasal tract visible in the rhinoscopic mirror, viz., the posterior nares.

If we examine the image of a normal posterior naris, as seen in the rhinoscopic mirror, we will observe a picture somewhat resembling Fig. 1.

Fig. 1. (a)

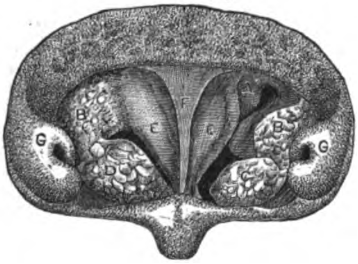


Rhinoscopic image of normal posterior nares. (Seiler.)

1. Vomer. 2. Free nasal passage. 3. Superior meatus. 4. Middle meatus. 5. Superior turbinated bone. 6. Middle turbinated bone. 7. Inferior turbinated bone. 8. Orifice of Eustachian tube.

In these openings are seen the posterior ends of the lower and middle turbinated bones, slightly scrolled and slanting, with their mucous covering; occasionally we get a view of a portion of the superior turbinated bone. Dividing these two openings we see the posterior portion of the vomer, wedge-shaped, with clearly defined surface gradually tapering to a narrow edge, as it joins the floor of the nose. Considerable spaces are observed between the turbinated bones, and between them and the vomer.

Fig. 2. (a)



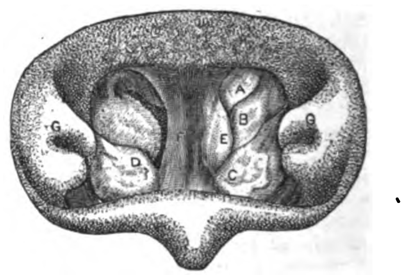
A. Superior turbinated bone (normal). B B. Hypertrophied tissue over middle turbinated bones. C D. Hypertrophied tissue over lower turbinated bones. E E. Hypertrophied tissue over vomer. F. Free surface of vomer. G G. Eustachian tubes.

If we now contrast this picture of the normal posterior nares with one such as is sometimes observed in cases of long-standing nasal discharge, a marked change will be noticed.

Fig. 2 illustrates what is often seen in the rhinoscopic mirror in a case of nasal catarrh of long duration.

Case I.—The patient from whom this drawing was taken was a man twenty-six years of age, of good parentage and of fair health. His history showed that he had always been easily affected by atmospheric changes, and that the nasal tract suffered most from these changes. For twelve years he remembered having a discharge from his nostrils, which, however, gave him but little concern. During the summer solstice the discharge was much lessened. Respiration had always been good, according to his statement, and at no time was mouth-breathing necessary; no attacks of asthma had ever occurred. For some years constant efforts to clear his throat have annoyed him. The post-nasal discharge was greatest when he became excited, and during the early part of the day. The secretion from the posterior nares was viscid and difficult of removal. Rhinoscopic examination revealed the conditions as seen in Fig. 2. Enormous hypertrophy of the soft tissues over the vomer on each side, extending its entire length; much greater above than below. The posterior end of the lower turbinated bone greatly hypertrophied on the right side, less on the left side; diffused thickening of the posterior end of the middle turbinated bone on right side. An hypertrophy resembling a collar projecting from the outer wall of left posterior opening, on a line with the middle turbinated bone, and springing from its outer portion. It will be noticed that on the right side, the spaces belonging to the posterior opening are so encroached upon by the hypertrophies that nothing but a mere fissure remains unoccupied; so that, practically, the right posterior naris is occluded, and can afford but little facility for the passage of atmospheric air during respiration. The left opening is less encroached upon, sufficient air appearing to pass through for respiratory purposes.

Fig. 3.



A. Hypertrophied tissue over superior turbinated bone. B. Hypertrophied tissue over middle turbinated bone (left). C D. Hypertrophied tissue over lower turbinated bones. E. Hypertrophied tissue over vomer, left side. F. Enormous swelling of the free surface of the vomer. G G. Eustachian tubes. Right middle turbinated bone shows diffused thickening.

Case II.—Is faithfully represented in the drawing, Fig. 3, which shows the same hypertrophic changes, with modifications, as are seen in Case I.

A. H. L., æt. 36, native, married, has enjoyed remarkably good health all his life; belongs to a wonderfully hardy stock, his father having died at a great age.

Fifteen years ago he first contracted an acute coryza, while exposed to very inclement weather. This coryza, which was severe in its onset, continued without abatement for fourteen years.

From the beginning of the attack he gradually grew worse, until after years of annoyance he was compelled to seek relief for the persistent and profuse nasal discharge. After many months of treatment, with but little mitigation of his disease, he abandoned all further medication, and resigned himself to his condition. For a number of years he endured his misfortune, continuing to grow worse. In the winter of 1881 he was compelled again to seek medical advice, when he came under my care. His condition was as follows:—Profuse serous discharge (a) from both nostrils, which required the use of *five dozen* large handkerchiefs per week; the almost constant use of handkerchiefs was necessary, so persistent and so profuse was the discharge. Respiration was entirely obstructed on the left side; the right side allowed a small quantity of air to pass through it, but not sufficient for respiration, which had to be carried on through the mouth. Extraordinary attacks of sneezing (b) often supervened, lasting for hours. These attacks of sneezing left him exhausted, and frequently occupied hours which were necessary for rest. In addition to this his nights were broken by repeated attacks of asthma, rendering it necessary for him to seek an open window for freer respiration. Attacks of

---

a *Medical News of Philadelphia*, April 7th, 1883.

(a) The serous discharge was greatly augmented by the presence of nasal polypi anteriorly.

(b) Partly dependent on the nasal polypi.

intense itching in the ear occasionally occurred. Thick tenacious mucus escaped from his post-nasal cavity, causing gagging, with oft-repeated efforts to dislodge it.

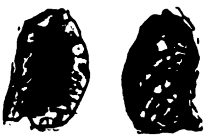
His voice was flat and nasal in character, with such a combination of distressing symptoms the patient's condition was deplorable.

Rhinoscopic examination was rendered extremely difficult by reason of great irritability of the fauces, and the soft palate was unmanageable from the patient's inability to breathe through the nose. After repeated efforts had been made, and an unlimited amount of patience had been expended, a satisfactory view of the posterior nares was obtained.

The appearance was unique in several particulars; marked hypertrophic conditions of the soft tissues over *all* the turbinated bones of the left side were seen; the same conditions were present on the right side over the lower and middle turbinated bones. The vomer was greatly hypertrophied on the left side. A most peculiar condition of the vomer was manifest, which I have never seen in any other case. In place of the wedge-shaped vomer, with the hypertrophy some distance within its free margin (as is seen in Fig. 2, and as is usually noticed), there was an entire change in the shape of the vomer, its normal outline being lost in an enormous infiltration, which extended upon all sides; the lower portion, where it joins the floor of the nose, was increased so much that it appeared of the same breadth as above, while the infiltration was flush with the free surface of the vomer. This swollen tissue was regarded as an infiltration or congestion, caused from obstructed circulation, which was produced by pressure of the hypertrophies, conjoined with the effect of an ever-existing rarefaction in the post-nasal space. Another most remarkable condition present in this case was an undoubted hypertrophy of the *superior* turbinated bone on the left side. The possibility of such a condition has been denied by very excellent observers, and to me was of so great interest that I made repeated examinations, lest an error in observation should occur. That this condition was present is indisputable. It is faithfully given in the illustration (Fig. 3).

The treatment of these two cases was in the main alike. As has been shown, the same pathological conditions existed in both. The treatment was essentially *surgical*. In my judgment *successful* treatment in hypertrophic nasal catarrh can be no other than *surgical*. Whatever treatment of a non-surgical character may be instituted, it can be considered as but an adjunct, and secondary to the demands of these cases. I believe that treatment consisting of the usual medicinal remedies, applied in whatever manner elected, is futile for the *cure* of hypertrophic catarrh, and does, at best, but temporarily relieve the distressing symptoms of cases where the hypertrophic change has progressed but little. But in cases of marked degree, even where respiration can be normally carried on through the nose, any other method than prompt removal of all this redundant tissue is an illogical and irrational procedure. The treatment carried out can be well illustrated by way of example (Case II., Fig. 3). The nose in this case was extremely sensitive, and intolerant of manipulation. At each sitting every attempt for many times was rendered but partially successful on account of prolonged attacks of sneezing, very often brought about by the introduction of the nasal speculum. All instrumental manipulation had to be done with the greatest delicacy and rapidity. As soon as an attack of sneezing supervened all work for that time had to be suspended. After repeated sittings the lower hypertrophy on the right side was engaged in the loop of a Jarvis's snare and removed. This gave considerable relief to respiration on that side. The left side offered prolonged resistance posteriorly to the introduction of the snare, because of the impaction of the hypertrophies in that orifice. After many fruitless endeavours a passage for the wire loop was made, and the middle hypertrophy was removed, then the one over the vomer, then the lower one. Fig. 4 shows two views of the hypertrophy after removal from the lower turbinated bone.

Fig. 4.



This made a marked change of the infiltrated vomer, which rapidly regained its normal shape and outline. As soon as the obstruction to the circulation had been relieved (by the removal of the hypertrophies), the hypertrophy on the superior bone decreased in size, and did not require any interference with the snare. After the removal of all these obstructions the breathing through the nose became free; mouth breathing was no longer required; the attacks of sneezing subsided, and asthmatic seizures were banished. His voice became resonant and normal. After the snare had done its work the galvano-cautery was employed to remove what general hypertrophic condition remained, to which the snare was not applicable. The amount of discharge gradually grew less during treatment, and finally became so little that a handkerchief was no longer a necessity. In cases of so marked degree as the above, I know of no method of treatment which would give such good results as were obtained in these cases by the use of Jarvis's snare and the galvano-cautery.

The successful management of cases of hypertrophy of the tissues over the vomer *posteriorly* has always been considered difficult, because of the situation; but in the galvano-cautery we have a remedy which renders the treatment easy and successful, and all other procedures appear cumbersome and inefficient in comparison. In a few sittings a marked hypertrophy of the vomer, and the train of unpleasant symptoms attached to this condition, can be made to disappear. In my experience no ill-effect has ever occurred. I have yet the first untoward complication to report.

To avoid secondary disturbances there are certain requisites, viz.:—1. A battery in perfect condition. 2. A very thin cautery knife. 3. Perfect adjustment to the part to be destroyed. 4. Contact of but a few seconds. 5. Thorough application of an antiseptic fluid to the parts cauterised.

◆

THE RECENT DECLINE IN THE DEATH-RATE, AND ITS EFFECT UPON THE DURATION OF LIFE. (a)

By NOEL A. HUMPHREYS.

The Registrar-General's mortality statistics prove beyond doubt that a marked decline has occurred in the national death-rate in recent years. There appears, however, to prevail a singular reluctance to accept this decline of mortality as evidence of the improved health and sanitary condition of the English people, or to recognise that it necessarily implies an increase of the mean duration of life in England.

The opponents of sanitation, prior to 1871, urged that the stationary death-rate was conclusive proof of the futility of sanitary labour and expenditure, refusing to recognise the fact that the death-rate was stationary in spite of the rapid increase of urban aggregation, as proof of the existence of a powerful counteracting influence. The late Dr. Letheby (although himself a health officer) and others went so far as to deny that a high death-rate was an unmixed evil. Dr. Letheby said that "an increase in the rate of mortality is often a sign of prosperity, for a high death-rate means a high birth-rate, and a high birth-rate is the invariable concomitant of prosperity." This theory was founded upon an entire misconception, but it was so satisfactory to the sanitary authorities of urban districts having both high birth and high death-rates that it was long before its fallacy was generally recognised.

(a) Read before the Statistical Society.

Now that an unquestionable decline in the death-rate has set in, considerable ingenuity is displayed in the attempt to question the advantage which results to the community from such a decline.

The question of the decline in the death-rate was discussed at some length in the Registrar-General's report for 1879, which was published in June, 1881, and attention was then called to two facts in connection with this decline; the marked decline in the death-rate in childhood, and coincidently therewith an increased death-rate among adults.

Attempts to explain these apparently contradictory facts seem to have suggested some of the false theories and unsound arguments which have been urged against the natural and true conclusions to be drawn from the decline in the death-rate. A leader-writer in the *Spectator*, in July, 1881, under the heading "Improvement of Human Health," asks, with reference to the decline in the death-rate, "What is the kind of life which is increasing, whether it is young life or mature life, or aged life, which is being enlarged? Are we young longer, or mature longer, or old longer?" These were and are reasonable inquiries, but the spirit in which the inquiry was made is shown by the context, "or, in fuller words, do we gain from all our costly and troublesome hygienic devices a longer period during which we retain the full energy of youth, or a longer duration of the period of wisdom——such as wisdom is—or a greater stretch of old age? Do we live longer, in fact, or are we only a little slower in dying?"

This article was followed by a remarkable letter from Dr. J. Mortimer-Granville, in which this line of thought was amplified with reference to a supposed analogy between the decline in the national death-rate and the increased duration of life in lunatic asylums under recently improved management. Dr. Granville urged that "the recent improvement effected by science consists in a prolongation of the passive endurance of life, rather than an extension of the power of true vitality or any increase of the opportunity for good work and for intellectual enjoyment." He deprecated therefore the excessive energy recently devoted to the conservation of health, and the inordinate and laborious means taken to avoid disease and death, and asserted that the pursuit of health and the yearning for longevity had become a craze, almost amounting to madness. No serious attempt was made in this letter to state the grounds on which Dr. Granville based his interpretation of the decline in the death-rate; it is, therefore, only important as a suggestion of the line of argument often adopted by those who disbelieve both in death-rates and in sanitation.

The main object of this paper is to determine, if possible, what will be the real effect of a continuance of the recent changes in the rate of mortality upon the duration of life in England. This should, to some extent, supply an answer to the inquiries suggested by the *Spectator*, and at the same time refute some of Dr. Granville's assertions. Before, however, addressing myself to the solution of this problem, it may be useful to refer briefly to one or two other efforts in the same direction.

A discussion on the subject was commenced in the *British Medical Journal* by three letters from Dr. Rabagliati, of Bradford, towards the close of 1881. Of the numerous other letters which have since been contributed to this discussion, none, however, call for special notice here except those of Mr. Biddle, of Kingston-upon-Thames. The results of the correspondence were mainly negative, although the letters both of Dr. Rabagliati and Mr. Biddle were full of technical interest, and displayed careful and laborious effort to solve the difficulty.

I propose to point out one or two of the flaws in the arguments of these two correspondents of the *British Medical Journal* before stating the results of my own investigations.

Finding that the death-rate is mainly reduced among children, Dr. Rabagliati assumed the impossible possibility of ten years each being added to the lives of ten millions of infants and children under five years of age who would otherwise have died, and asks, "At the end of ten years how much the better should we be?" This of course assumes the extinction of all these lives at the end of the ten years; but is this a fair assumption? Why did not Dr. Rabagliati investigate the effect of the survival of these millions of infants during the ten years, to be afterwards liable to the usual death-rates at subsequent ages? Then Dr. Rabagliati's attempt to use the mean age at death to support his assertion that the recent saving of life was confined to childhood, led him to completely false conclusions.

Mr. Biddle, in his elaborate paper, arrived, on the whole, at sounder conclusions than Dr. Rabagliati as regards the duration of life in England, for he says, "So far as the useful years of life are concerned, there is no doubt that a greater proportion of those who are born live through them;" and after a careful examination of the question propounded by Dr. Rabagliati, is of the opinion that "the state of things is not so bad as he has tried to make out."

We will now proceed to consider the extent and nature of the recent decline in the death-rate, and then to estimate its effect upon the lifetime of a hypothetical generation, or what may be called a Life Table population.

I.—*The Decline in the Death-Rate.*

It is scarcely necessary to say that very little is known of the variations in the annual death-rate in England prior to the establishment of civil registration in 1837. The Registrar-General's mortality statistics embrace the forty-five years 1838-82, and constitute the only trustworthy basis for calculations as to the duration of life in England.

Although the death-rate varied from year to year, it may be said to have remained practically stationary during the thirty-three years 1838-70. The extreme range during this period was from 24·7 and 25·1 in 1847 and 1849, to 20·5 in 1856. The high rates in 1847 and 1849 were due to epidemics of influenza and cholera. If we divide this series of years into what we may call census decades, we shall find a remarkable equality in the mean death-rates. The rate averaged 22·3 in the three years 1838-40, 22·4 in the ten years 1841-50, 22·2 in the ten years 1851-60, and 22·5 in the ten years 1861-70.

It has been previously stated that the absence of decline in the death-rate prior to 1871 was frequently urged as evidence of the futility of sanitary efforts, the counteracting influence of rapidly increasing urban aggregation being entirely ignored.

Early in the most recent decade, 1871-1880, the Public Health Act of 1872 became law. The passing of this Act, and the further Act of 1875, marked an eventful epoch in the history of sanitary progress in England, and it appears impossible to doubt that the operation of these Acts, themselves due to the awakening of national interest in health matters, has proved a powerful factor in the recent marked decline in the death-rate which we are now considering.

The mean death-rate in the five years 1871-75 fell to 22·0, and in the following five years, 1876-80, it further fell to 20·8. For the purposes of this paper our consideration will be mainly confined to the reduced death-rate in the five years 1876-80, but we may here note that this marked decline was more than maintained in the two following years, 1881 and 1882, when the unprecedentedly low rates 18·9 and 19·6, were respectively recorded. Thus the mean death-rate in the first two years of the current decade, 1881-90, was so low as 19·3 per 1,000, implying that more than 150,000 persons survived those two years, whose deaths would have been recorded had the mean rate of mortality that prevailed in the thirty years 1841-70 been maintained.

II.—*Relative Mortality of Males and Females.*

A word or two on the relative mortality of males and females is now desirable. In 1876-80, as in 1838-54, the rate of mortality among males exceeded that which prevailed among females at each of the twelve groups of ages except in the two quinquenniads between 10 and 20, when the rates among females exceeded those among males; but as the decline in female rates at these ages in 1876-80 was greater than among males, the actual excess of the female over the male rate did not exceed 1·7 per cent. at the 10—15 group, and was not more than 3·5 per cent. between 15 and 20.

At each of the other ten age periods the rate among males showed in 1876-80 a larger excess than in 1838-54; the excess at all ages being equal to 13·4 per cent. in 1876-88, against but 7·4 per cent. in 1838-54. If we examine the varying excess of male mortality at the ten age groups at which an excess prevailed in 1876-80, we find that it was equal to 18 per cent. under 5 years of age, was 8, 9, and 10 per cent. at 5—10, 20—25, and 25—35 respectively. The excess of male mortality at each of the three next decenniads was much larger, and equal to 20, 27, and 20 per cent. respectively. After 65 the relative excess of male mortality fell again, being 12 per cent. at 65—75, and 11 per cent. both at 75—85 and 85 and upwards. A most marked change occurred in the relative mortality of males and females aged 25—45 between the two periods under notice. At 25—35 male mortality in 1838-54 was 5 per cent. below, whereas in 1876-80 it was ten per cent. above that prevailing among females; at 35—45 the excess of male mortality was only 0·5 per cent. in 1838-54, whereas it had risen to 20 per cent. in 1876-80. These changes in the relative mortality of males and females are due more to the increased vitality of females than to the increased mortality of males.

III.—*Mean Duration of Life, and Mean After-Lifetime (Expectation of Life) at Various Ages.*

Let us now see to what extent and in what manner the duration of life, and the expectation of life at various ages would be altered by a continuance of the reduced rates of mortality that prevailed in England during the five years 1876-80.

Dr. Farr's Life Table made the mean duration of life or mean after-lifetime of males at birth 39·91 years, whereas the new Table raises it to 41·92 years, an increase of rather more than two years, equal to the addition of 5 per cent. to the mean duration of the lifetime of males. The mean after-lifetime of females, which according to Dr. Farr's Life Table was 41·85 years, is extended by the new Table to 45·25, representing the addition of no less than 3·40 years, or more than 8 per cent., to the average lifetime of all females born.

The mean lifetime of a generation of persons (the sex proportion being fixed by that of births of live-born children) was determined to be 40·86 years by Dr. Farr's Life Table, whereas the new Life Table raises it to 43·56 years, showing an increase of 2·70 years, equal to nearly 7 per cent. Thus the reduced death-rate, if the reduction be maintained, signifies the average addition of a fifteenth to the lifetime of every infant born.

In a population like that of England, however, the recorded death-rate at all ages (owing to the abnormal age constitution of the population due to the excess of the birth-rate over the death-rate) is considerably below its true death-rate after correction for abnormal age constitution.

But to return to the consideration of the expectation of life in England at different ages, as affected by the recent decline in the death-rate. We have seen that at birth the expectation of males is greater now by rather more than two years than it was in 1838-54. This increased expectation decreases steadily at each age with the decrease of the proportional decline in the death-rate. At the groups of ages 35—75, indeed, in which the death-rate of males was higher in 1876-80 than in 1838-54, the expectation of life is actually lower than it was, thus corroborating the letter though not the spirit of Dr. Rabagliati's statement that "the expectation is less now for useful ages than it was."

The increased expectation of life of males at 20 falls to 0·38 of a year, and at the four next decennial age periods the decrease of life expectation ranges from 0·07 to 0·52 of a year; after 75 years a slightly increased expectation again prevails.

The increased expectation of life of females at birth is, as we have seen, 3·40 years. This declines steadily at each successive age period to 0·15 of a year at 45, and at age 55 the expectation, owing to the increased death-rate, shows a decline of 0·06 of a year. The expectation of female life at 65 years and upwards again shows an increase, due to the decline in the death-rate at these ages.

So far our examination of the new Life Table teaches us that the true import of the reduced death-rates of 1876 80 is an increased expectation of life at birth of two years among males, and nearly three and a half years among females.

IV.—*Dependent and Useful Lifetime.*

The reason why the national gain arising from the recent general decline in the death-rate has been undervalued is, that whereas the increased death-rate of males aged 35—75, and of females aged 55—75, are simple facts, and therefore easily comprehended, the other fact that a larger proportion of those born survive to the useful ages is not so easily measured and appreciated. Let us therefore now, with the help of the figures in Table VII, consider the increase in the numbers of survivors at different ages, due to the recent decline in the death-rate. Of each 1,000 males born, forty-four more attain the age of 35 according to the Life Table of 1876-80 than by the previous Table of 1838-54.

Notwithstanding the slight increase of mortality among males aged 35 and upwards, a large proportion of these additional forty-four survivors live on to the higher ages. Of the 1,000 born the additional number of survivors is thirty-five at age 45, twenty-six at age 55, nine at 65, three at 75, and one at 85. This clearly proves that the gain to human life is not confined to childhood and youth. Although males over 35 years die at a somewhat higher rate than formerly, the marked decline in the death-rates up to that age causes such an addition to the number of survivors above that age, as materially to increase the number of years lived at all the subsequent ages.

This increase in the number of survivors to adult and middle ages is of course much larger among females than among males, owing to the much greater decline in the death-rate of females. Thus of 1,000 females born, sixty-one more attain the age of 45 by the Life Table of 1856-80 than by that of 1838-54. The additional survivors among females, by the more recent Life Table, are fifty-seven at age 55, forty at 65, twenty at 75, and six at 85. These figures show in a conclusive manner that much larger proportions both of males and females now survive to and live through the useful adult ages than survived thirty years ago.

When we consider that nearly 900,000 births occur annually in England and Wales, and that the effect of this reduction in the death-rate signifies the addition of 900 times 2,699 years of life to the lifetime of the English people each year; and further, that 66 per cent. of these years of added life are lived at the useful age period 20—60, it becomes possible to realise how vast will be the national effect of this reduction in the death-rate.

It would be impossible within the limits of this paper to attempt to discuss the causes that have most largely contributed to the changes that have recently taken place in the English death-rate, namely, the marked decline in childhood and youth, and the small increase in middle life. Dr. Rabagliati attributes the former mainly to the decreased fatality of zymotic disease, and the latter to the increase of anxiety and worry arising from intensified competition and struggle for existence. There is probably much truth in these assertions, but further investigation will probably show that decrease of zymotic fatality will account for only a portion of the marked decline in the English death-rate of males between 5 and 35, and of females between 5 and 45 years of age. We cannot implicitly accept Dr. Rabagliati's assertion that if zymotic diseases be excluded, human life can be shown to have actually shortened in recent years. Assuming, however, (what is probably to a great extent true), that the lowered death-rate and increased duration of life that we have been discussing, are in great measure due to the reduced fatality of zymotic diseases, these changes are none the less a national gain. Moreover, we doubt if Dr. Rabagliati has taken sufficiently into account the fact that if children be spared from the ravages of these preventible diseases of youth, one of the natural results of their survival is to render them liable in after years to the diseases incidental to adult life. This subject is, however, quite beyond the scope of the present paper.

◆

THE PHILOSOPHY OF VOICE.

By CHARLES LUNN.

Ten years have passed since I had the honour of making in the *Medical Press and Circular* (*a*) the first attempt to weld into a science the conflicting thoughts and opposing statements that then on voice-production obtained. And I propounded the hypothesis that voice training—that is, voice re-setting and voice development —is the work of a surgeon, not of a musician, the education of the former being more adapted to it while the developed sensibility of the latter is a direct impediment to it. The surgeon has only to have a rightly-trained voice to be able to demonstrate both true and false production, while his intellectual culture would enable him to join precept to example. With the view of gaining a number of helpers whose precepts science endorses, and whose personal art demonstration in after time would meet with natural acceptance by all persons possessing musical ears and cultured minds, those papers were then written. That good and evil have each come therefrom is clear, so now a brief retrospect is needed to show the loss and gain.

At the time of my writing no one had attempted to give a reason why the human voice in the adult requires training, the accepted view being that Nature made man defective and false. I went to show that, just as bad type will produce a physical injury to the eye, so spoken words will produce a physical distortion in the organs of voice. And this struck a new field of philological research, and accounted for the accidental repute and conflicting statements of many teachers, who, having trained musically pupils with true voices retained, obtained credit thereby as competent to restore to others their disturbed nature. Secondly, as the voice organs in man and woman are similar in form, and, as musicians allege, they are not identical in register, this conflict between physiologists and musicians I explained away by tracing the acoustical difference to difference in thoracic form and modes of breathing; and these physical differences, I ventured to suggest, were made by Nature for obstetric reasons.

History tells us the old Italian school of Porpora and the elder Garcia obtained uniformly nearer three than two octaves of notes, two octaves being the minimum admissible compass. The silent evidence supplied by the writings of dead composers proves they had then voices of such compass (see Boosey's "Opera Albums"), and experiments with the detached larynx corroborate this compass. This old school, secure in its results, was content with its facts, but its representatives gradually became fewer before the inroads of pianists who vicariously undertook the art of voice training in conjunction with their own. It is to Emanuel Garcia we are indebted for the salvation of such of its truths as we have (circa, 1840), and in him we get the point of departure when he gave up distortion and strain of voice under laryngoscopic observation in order to retain quality of tone. The laryngoscopic proposition before E. Garcia was this—he had either to annoy his ear by harsh sounds to gratify his eye, or to be content with such restricted vision as Nature inviolate accorded him, knowing that any "unnatural drawing back of the epiglottis" (Seiler, p. 40) must disturb conditions for true vocal emission and falsify voice, and that disgrams from such disturbed conditions represent the voice organs producing noise, not artistic sound. The proposition, or rather challenge, to which I am about to lead up, is this—Can we, by welding together known parts of physiology, natural physics, acoustics, and philology, found a school of training?

Here is the history of divergence: From Garcia's discovery of the laryngoscope two classes of observers sprang —one class trusting to ocular demonstration at any physical effort, the other class, believing voice a thing to be heard and not seen, trusting to auricular concurrence and logic. Of these observers, about some twenty years ago, there were two specially prominent—one in Germany, one in Scotland—each honestly working faithfully to obtain information about voice in action. One, Madame Seiler, took the laryngoscope and attached larynx strained; the other, Dr. Wyllie, took the excised larynx, and attempted to follow the mechanical laws therein. But the judgment of a trained artist had not at that time come. Now, Dr. Wyllie supplied a "cross proof," to use Prof. Huxley's words of my earliest text, of the old school of voice-production; Madame Seiler a condemnation of it. Dr. Wyllie proved there is a check action in the larynx, and so he accounted for the ease, the compass, and the endurance of the old singers and of our modern best; and Dr. Gordon Holmes lately discovered that the great old physiologist Galen held the same truths on voice, so that, as the experiments of Majendie and Müller went to corroborate Galen's suggestion there are two kinds of nerve, so now our experiments and our observations on trained singers go to sustain Galen's statement that the glottis is a double valve. By kind permission, I reproduce Dr. Gordon Holmes's translation, with his brief introduction.

"The views of Galen on this point (ventricular influence) illustrate well the remarkable scientific acumen of that indefatigable observer, and are interesting on account of having been recently revived by Wyllie quite independently from experimental considerations. And that an important function of the ventricles of the larynx has been indicated by both authors cannot, I think, be doubted by any one who has paid full attention to the question." And here, quoting Galen, "But this body (*b*) of the glottis is not only necessary to the organ of voice, but also to what is called holding the breath . . . to which action the nature of the aforesaid glottis contributes not a little, for to effect the said purpose the parts of it of the right and of the left approach, so as to fall together accurately, and close the passage. But should a small portion be left enclosed, not even this, as being unforeseen, has been disregarded by Nature, who has worked an opening on each side of the glottis, and placed in continuity with the aperture a cavity within by no means small. When, therefore, the air, making use of a wide channel, goes into the animal, and passes out again, none of it is turned aside into the cavity. When, however, the passage out is blocked, the air, being confined in a narrow space, is diverted forcibly towards the sides, and opens the mouth of the aperture of the glottis, which

---

(*a*) Much of what I have written and am about to say, if solely addressed to the members of the profession, will appear redundant, if not impertinent; but the subject upon which I venture to treat is of such great importance, and so much wealth is risked thereon, that I have dared to address, through them, a wider constituency. I trust, therefore, that what may appear superfluous to the special class to whom I immediately appeal may be forgiven me for the greater number whose welfare is involved.

(*b*) Galen considers the "body" which he calls glottis to consist of the vocal and ventricular bands of both sides, with the ventricles between them.

hitherto has been closed by the folding together of the lips. The cavities in the glottis of the larynx being thus filled with wind, it is, of course, necessary that the swelling so produced should bulge towards the passage of the breath, and shut it with exactitude, even if a small part had previously been left open" (Oribasius I, xxiv., c. 9.).

And here, Wyllie: "The physiology of these ventricles, and of the superior ligaments of the larynx is thus, after all, so beautifully simple as to render it very surprising that their action was not long since recognised."

We may now go a step further. This physical description by Galen is the only one that fits a vocalist's experience, and under such experience the sound-producing parts cannot be entirely seen. On the other hand, if Madame Seiter and her representatives who are now putting out photographs of the vocal organs "in the act of singing" be true, then the pictorially reproduced voice must be acceptable to an ear as a beautiful sound! Of course, such photographs may be interesting to some —they are not to artists—but only by comparing them side by side with the voice producing them, which must of itself be beautiful, can they be of service to the public. Under laryngoscopic observation it is impossible for me to produce a note of any musical value; nor is such sound as that produced capable of accurate response to will. The testimony of known artists will, of course, be of far greater value than my own unsupported word, so, before proceeding to strengthen my past arguments by additional proof, the following extracts from letters with which I have been favoured should be read:—

Mr. Maas writes: "My experience is that, when required to sound my voice with the laryngoscope inserted at the back of my mouth, it is utterly impossible for me to make a vocal sound; the only utterance I can make is a noise like the baa of sheep, or rather like one would imagine the sound would be in strangulation."

Mr. Santley writes: "Some few years ago I did try to produce a note while my medical man was examining my throat with a laryngoscope. I could not produce much sound, and what there was I should say was decidedly unmusical."

Mr. Sims Reeves is even more emphatic, and lays his finger on a deep metaphysical point which our cruder materialistic photographers seem incapable of appreciating. He writes:—"My advice is, let the laryngoscope alone. Students who wish to learn to sing had better apply themselves to the Art. It is my opinion that a singer should avoid looking down his own throat, too intimate a knowledge of the mechanism of the same would render him nervous and timid." Compare this with what I wrote in the *Medical Press*, 1873:—"It is better to illustrate by abstraction, as physiological sketches are, to the living subject, useless for teaching purposes, and indeed confusing rather than aiding."

Madame Nilsson has also referred to this metaphysical side: "At the least unexpected event, especially if it be anything of the nature of a disappointment, she may become hoarse, and her vocal organs refuse to respond. It has been found absolutely impossible to train the voice sufficiently to enable it to overcome such causes of depression."

It may be advanced, as against this evidence of artists, that although the voice under laryngoscopic strain sounds "harsh," that this is owing to second causes, the instrument blocking the caverns that multiply created sound; and that, therefore, there is no reason to suppose but that the organs act the same under modest neglect as obtrusive observation. This hypothesis is disproved by the fact that trained singers can produce the same unmusical note at will when the laryngoscope is withdrawn.

The question before physiologists is—"What are the physical differences in the organism when producing musical and unmusical sounds?" Or, to put it another way—"What are the physical differences between a wrong note seen and a right note unseen?"

(*To be continued.*)

Clinical Records.

ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

Under the care of Mr. WILLIAM BERRY.

Case I.—*Deformity of Femur after Fracture—Forcible Straightening.*

J. B., æt. 26, admitted November 25, 1882. Six months previous to admission the patient had received a fracture of the left thigh bone at the junction of lower with the middle third. This had been treated with a long splint for two months, and the patient returned to work with a comparatively straight limb four months after the accident. He says that it gradually bent, and got weaker. On examination a large amount of callus was found around the seat of fracture; there was two and a-half inches of shortening, and the bone seemed firmly united at an obtuse angle. On the 14th December, 1882, osteotomy was proposed, and the patient was placed under chloroform. Before operating, however, it was considered advisable to try the effect of forcible pressure. After applying a great amount of pressure, it was found to have straightened somewhat. A long splint was then applied, and a piece of gutta-percha moulded over the seat of fracture was firmly bound on. This treatment caused absorption of some of the callus, and resulted in the straightening of the limb after an application of four weeks. The patient was discharged on January 17, 1883, with the limb considerably straighter and a trifling amount of shortening. Three months afterwards he was seen, and the union was found to be quite firm, the leg straight, and the man walking with very little lameness, and shortly after this recommenced his ordinary work.

Case II.—*Sarcoma of Superior Maxilla (Left)—Removal—Recovery.*

Betty H., æt. 68, admitted February 17, 1883.

Family History.—Mother's brother and patient's sister died from cancer of breast and lip respectively.

History of Case.—Patient has always enjoyed good health until seven months ago, when she noticed a small lump over left lateral cartilage of the nose. During the last three months the lump increased rapidly in size, but without pain. About a month ago a little discharge of bloody serum escaped from nostril. On puncturing the tumour, which now had become painful, and was blocking up the eye, nothing, except a little blood, escaped. On further examination, the left nostril was found to be filled with the tumour, the growth extending two inches to left of median line of nose, one and a-half inches from free edge of alveolar process of jaw to half-an-inch from inner canthus of left eye.

On February 22nd the tumour was removed by the ordinary incisions and by dissecting back the flaps, then by dividing with bone forceps the nasal, alveolar, and palate processes of maxillary bone, the tumour was then easily removed with the bone.

The wound in the face healed rapidly, and the patient was discharged on March 18th cured.

Case III. — *Ovarian Tumour (Multilocular) — Removal — Recovery.*

E. H., æt. 57, married, and mother of a large family, admitted April 23, 1883.

History.—About twelve months ago she noticed an enlargement of the abdomen, chiefly on the left side. This was occasionally painful, and gradually enlarged, until it assumed its present proportions. She now finds it burdensome to move about, and has to lie on her back in bed for comfort. She measures forty-seven inches over the umbilicus; the skin is stretched, and white spaces are well marked. Notwithstanding the fact that her appetite has been poor for some time, and although everything she has latterly taken has been rejected, she has not lost much flesh. At intervals of three, and sometimes of six weeks, a discharge (sometimes lasting for a week) resembling menstrual fluid takes place. The bowels are rather constipated. On examination per vaginam, the uterus was found somewhat drawn up, the os patulous, but the cavity admits a sound to its normal length.

On the 10th of May the patient was placed in a special ward. Chloroform was administered. The bowels and bladder having been previously emptied, an incision about six inches long was made, and the parietes were found thickened with adipose tissue. Before opening the peritoneum, it was sepa rated from the sheath of the rectus to a slight extent by mistake. After opening the peritoneum, the tumour being exposed, a few adhesions were broken down, and a Spencer Wells' trocar introduced, but the contents of the sac being gelatinous did not escape. The other cysts were then emptied by a long trocar and canula, by which means about six quarts of dark grumous fluid were removed. The tumour was then drawn out through the abdominal wound, and the pedicle found to be very short, and closely attached to left side of uterus. This was secured with silk whipcord and divided; the pelvis was sponged free of all fluid, and pedicle dropped into the cavity. Before closing up the wound, it was found that the pedicle allowed some oozing; it was therefore taken up, and ligatured in three portions very firmly. After all oozing had ceased, the edges of the wound were brought together by deep wire sutures about one inch apart, including the peritoneum in them. One of Keith's drainage tubes was placed to the bottom of the pelvis at the lower angle of the wound. An absorbent pad of cotton wool and a flannel binder were then applied. A morphia suppository was given, and the patient placed back to bed, with hot tins to feet, and well covered with a blanket.

One teaspoonful of brandy with soda water was given every two hours.

Evening.—Pulse 120, temp. 100·2.

May 11th.—Pulse 108, temp. 99·2, in morning. Patient passed a good night. Evening: pulse 108, temp. 100·2. Patient a little sick; a suppository of morphia ordered night and morning, and for food a little chicken broth.

12th.—Passed a pretty good night. Temp. 99. A good deal of discharge in the pad, and about an ounce removed by syringe through the drainage tube. Evening: temp. 100·2, pulse 130.

14th.—Dressed yesterday and also to-day. A good deal of discharge in pads. Wound looks very well.

17th.—Still improving. Takes food (chicken broth), with soda water and brandy. Brandy now reduced to six ounces daily. Evening temp. since May 14th, 99, and pulse 100. Drainage tube removed on 16th.

19th.—Wound almost healed, except where drainage tube was inserted. All sutures removed. A good deal of discharge from this opening; looks as if the wound itself discharged freely. Morning temp. 98, pulse 94; evening temp. 99·2, pulse 104. Takes two or three glasses of koumiss in the day, and plenty of chicken broth. Bowels not moved, but sleeps well.

21st.—Feels uncomfortable for want of bowels being moved; inclined to be sick. Morning temp. 97·6, pulse 96.; evening temp. 99, pulse 104. Ordered to have a little codfish; to have three grains of calomel night and morning till the bowels are properly moved. Patient passed a little motion with pain last night. Ordered suppositories of belladonna instead of morphia.

22nd.—An injection of warm water was given, but very little fæces came away. Wound discharging as usual. Patient feels sick.

23rd.—Passed two motions in the night (liquid). Calomel stopped. Patient had some codfish, and feels more inclined for food. Takes egg and milk daily. Morning temp. 97·8, pulse 95; evening temp. 98·4, pulse 97. Wound still dressed every day with dry pads and a flannel bandage.

25th.—Had a lamb chop. Keeps well. Ordered a quinine mixture.

Patient now progressed uninterruptedly, and was discharged on May 14, 1883, cured. The wound where the drainage tube had been was not quited healed.

Remarks by Mr. Berry.—In Case I. we had a very favourable result by forcible pressure and extension, and by pressure over callus with a splint firmly applied. In cases like these I should strongly advise this before performing osteotomy.

In Case II. it would have appeared scarcely worth while undergoing the risk of an operation considering the age of the patient, but the comfort and improved appearance, however, amply justify what was done.

In Case III. we have a proof of what the peritoneum can stand. No doubt the separation, which was unfortunate, prevented earlier closing of the wound. A good result was obtained by careful nursing; attention to the bladder every three or four hours by the catheter for the first few days, perfect rest being insisted on. Keith's drainage tube was very useful, and I think to this free drainage much of the good result was due. Koumiss was much liked by the patient.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

Diabetes.—At the meeting of the Academie de Médécine a member read a report on the treatment of diabetes by bromide of potassium. According to this communication, bromide of potassium would form a good adjuvant in certain cases, but as it had a very depressive effect on the system it should only be used concurrently with other remedies which would raise the tone of the constitution. M. Bouchardat agreed with the author of the report. He believed that the salt in question was useful in certain cases, but should be used with prudence. He thought that preference should be given to *régime* and gymnastic exercises. M. Lanier said that in the cases of children and the aged, bromide of potassium should not be used. M. Hardy could not adopt the views of his colleague; he obtained very good results from the bromide in diabetes. He gave it in the dose of a drachm daily, and instead of the strength of the patient diminishing under its influence, it increased. The opinion of your correspondent, who has had the opportunity of using it in this malady is that it certainly is of great use, as it effectually calms the great agitation of the patient, especially at night, when the great thirst prevents sleep.

Colotomy is an operation very rare in France, as the French surgeons have considered it a dangerous and useless operation. M. Pollaillon brought a case under the notice of the Academy. The subject was 21 years of age, who had a hernia on the left side since infancy. Two years ago the hernia became irreducible, and a neuralgia of the testicle of the same side, which was attributed to the weight of the tumour. No bandage could be borne under these circumstances. M. Pollaillon attempted the radical cure with an entire success. M. Guérin criticised the operation of M. Pollaillon, which, according to him, was not equal to his own, which he practised over forty years ago, and which consisted in practising a series of subcutaneous wounds, the exudation resulting formed a cicatricial tissue which completely obstructed the canal, and thus effected the radical cure of hernia.

Typhoid Fever and Ether.—A provincial doctor has published five cases of typhoid fever treated by subcutaneous injections of ether, which he considers as the best mode of administering stimulants in the adynamic forms of the disease. Two injections, of twenty drops each time, were made daily, and under its influence the patient was aroused and delirium ceased. In pneumonia, these injections are of the greatest utility, as they are in every malady assuming a typhoid form.

Copper Plates as a Prophylactic against Cholera.—M. Burcq, the great metallotherapist, recommends the application of copper plates as a prophylactic against cholera. His experiments were founded on the innocuity observed from that disease amongst the workmen of the great copper works of Toulon during the epidemic of 1865. Of 300 workmen who continued to work but one fell a victim to the disease, and this man had left off a few days previously. M. Burcq, who relates his personal observations of that period, recognising the effects of the metal upon the malady determined to put the matter to the test, and for that purpose went deliberately into the most infected quarters armed with over 50 discs of copper which, applied closely to the skin, resembled a coat of mail. Besides these plates he took the sulphate of copper internally, by the mouth and by enema. The action of the cupric salt was to produce an obstinate constipation, which, however ceased immediately on the suppression of the treatment. The conclusions of the report of M. Burcq are as follows :—All sheds destined to receive cholera patients should be saturated with a solution of sulphate of copper. The bed, covering clothes, &c., should be dyed with a solution of the salt. Disinfection of all dejections with a five per cent. solution. As to individual preservation, he recommends a belt of copper plate to be worn around the body, and garters of the same metal on the legs. Further, a flannel shirt dyed in a strong solution of copper should cover the chest and abdomen, and from one to six of the following pills should be taken daily :—Bioxide of copper, 18 grains ; extract of liquorice, 3 drachms ; divide into 100 pills. The author is confident of the success of this treatment.

◆

PERSONAL EXPERIENCES OF THE CHOLERA EPIDEMIC IN EGYPT.

The following narrative by Mr. F. Ernest Taylor, M.R.C.S., who was one of the medical staff sent out to Egypt by Her Majesty's Government, will be read with nterest.

Mr. Taylor arrived at Alexandria on August 2nd, and proceeded at once to Cairo, which city he reached on the following day. Cairo was in a state of panic. After an interview with Salim Pasha, President of the Conseil de Santé, and Baker Pasha, he and his fellow surgeons got their orders to start for their different destinations. On the 6th Mr. Taylor, with Dr. McNally, started for Zagazig, accompanied by their dragoman. On reaching Zagazig they started on a tour of inspection, but found the "house" which the Mudir had provided for them a most unsavoury place of residence, it being situated in the middle of mud huts, and little better than its environs. They naturally refused to take up their quarters here, and returned to the station, where they fortunately secured two empty rooms. But even here their experiences were the reverse of favourable, bats, mosquitoes, and sandflies combining to render sleep out of the question. Early on the morning of the 8th they went out to see the cholera cases, and one of the first pieces of information they received was that the native doctors had run away at the commencement of the epidemic. They found five cholera tents pitched outside the town. The wretched patients, who were for the most part prisoners in chains, had not been seen by doctors for two days, and had had no medicine. The heat underneath the tents was horrible. Mr. Taylor observed that most of the cholera cases in Egypt were in the huts, the poor people having a great dislike to the hospital. They next proceeded to the General Hospital, and found ten or a dozen men suffering from various diseases, but no cholera, and the condition of the institution was such that English doctors could well understand why the people had a horror of it. The sight which met their gaze beggared description. The filth and dirt were disgusting, and the stench suffocating. They found a woman in the deadhouse cooking the breakfast a yard from an open *latrine*, and this latter experience they found to be the rule rather than the exception throughout Egypt in the poorer houses. After breakfast they started for the cemetery, which they found very crowded, learning on good authority that the official reports as to the mortality were incorrect, the number of deaths greatly exceeding the numbers stated. They found that the bodies were not buried (except in those cases where the deceased were rich) more than one foot in depth, and as a consequence the jackals dig them up in the night time. The stench here, again, was horrible, and in the middle of the cemetery a man was observed drawing water for drinking purposes. Mr. Taylor goes on to say : "I believe there is some religious feeling prevailing that water here (in the cemeterg) is holy ! No wonder cholera is spreading. Religion is the greatest obstacle we have to contend with, especially amongst the poorer and less educated classes. Their belief is one of pure fatality. 'You cannot fight against God' is their cry, and some regard it as perfectly impious to administer medicine. One man told me 'if God meant him to die he would die, and if he were to live he would live,' and so he refused medicine." The chief doctor in this neighbourhood was an Arab, and a man of European education, but as he did nothing to assist the English surgeons he was discharged forthwith. It was found that scientific medicine was impossible, and so the Englishmen became more "scavengers" than doctors, but notwithstanding their limited opportunities they became very successful in their treatment, hypodermic injections of morphia being especially beneficial in allaying the pain of the cramps. By the 12th of August they got the town in a little better order, thanks to the powers with which they had been invested by the authorities. The hospital was whitewashed, and its floors, which were mud, boarded, whilst fresh windows were put in, and some huts adjacent were burnt down. The streets were, moreover, well cleaned, swept, and watered ; whilst a great number of buffalo carcasses, which had been allowed to accumulate because the people wished to avoid a tax which is levied upon every head of cattle that is interred, were liberated from the stream, and sent, as the doctors hoped, out to sea. In this good work much valuable assistance was lent by Col. Oliver, chief of the gendarmerie. It had by this time been discovered that typhoid fever was rampant, and this was scarcely to be wondered at, seeing the recklessness with which the people poisoned the water.

At Sirwias it was found that the main drain opening into the canal, the water in which, though at this time of the year as thick as pea-soup, was drunk indiscriminately by all classes, and in great quantities, without being filtered or boiled. Mr. Taylor expresses the opinion that the water in some of the small villages, especially in Upper Egypt, where the streams are smaller and less rapid, must be pregnant with typhoid germs. On the 14th cholera was found fast declining at Zagazig, and Mr. Taylor was summoned to Cairo by Salim Pasha, and ordered by him to proceed to Fayoum, in Upper Egypt. The latter place he reached on the 17th, whither he was accompanied by Fadir Bey, a professional gentleman of whom Mr. Taylor says, "that he knows no English, very little French, and still less of medicine." At Fayoum, he found himself the only European out of a population of 35,000. Here, the native doctors did not present a higher standard of proficiency than in other places. Their ignorance, except in a few cases, was extreme. They are, it appears, very badly paid if holding a Government appointment, and consequently do nothing without "backsheesh," a state of things which necessarily falls hard upon the poor people. Mr. Taylor divided the Fayoum district into four parts, and having supplied each of the native doctors under his charge with medicine he sent them off. On the 19th he went to Linoris, a distance of twelve miles, his *modus operandi* during the journey being as follows :—He carried medicines with him, which he gave to such "cases" as he saw, and left medicine with them. Then, through his dragoman, he read them a short sermon on the best plans to follow in the matter of sanitation. A day or two later he visited a place called Agameen, about nine miles from Fayoum, where he found the people very dirty in their habits—so dirty, indeed, that he abruptly told the Sheik that if the village were not cleaner when he came again he would have him punished.

Mr. Taylor continues:—"It is not my province to dwell upon the internal administration of Egypt, but I can only say that knowledge procured by living at Cairo is quite as trustworthy as that got by residing in London. The people don't know who to look up to as their rulers, and the whole affair seems to be a perfect farce from beginning to end, the people looking with distrust at the 'puppet,' which is made to move with an invisible hand behind it. The Arab people (by people I mean the poor) are very harmless, and are mere children in their ways. They can be more easily led by a kind word than a kick, and seem to understand a pat on the back more than a blow. If you hit one, he is, of course, terribly frightened; whether or no this is due to a reminiscence of late date I am unable to say. Up to the present our work has been very arduous, and I am afraid what good we have done has been but the proverbial 'drop in the bucket.' The drawback to treatment here is having to go from mud-hut to mud-hut. You go into a room reeking with filth, and there you find man, woman, or child as a rule, in the collapse state of cholera. They never think of sending for a doctor before you raise them from their filth and dejection, and administer medicine. You are attending, perhaps, to thirty such cases, and it is impossible to stay with one. The consequence is if you leave medicine to be taken it is never given. It must be distinctly understood that Arabs never take medicine, and the poorer people think European doctors wish to poison their patients. In fact, a doctor is not thought much of in Egypt. There is no doubt of one thing. It is very satisfactory to say that Egypt has never been so clean as it is at the present moment, and although we have saved comparatively few deaths, the numbers being so great, I thoroughly believe the English contingent, including the army officers, have been instrumental in preventing the further spread of the disease."

INTERNATIONAL MEDICAL CONGRESS AT AMSTERDAM.

The International Medical Congress opened its proceedings at Amsterdam, on Wednesday last. The attendance was very large, delegates having arrived from almost every civilised country on the globe, and amongst the representatives of England were Sir Joseph Fayrer, and Drs. Dyce Duckworth, Barclay, and Scriven, of London; Professors Lewis and De Chaumont, of Netley; Dr. Ewart, of Brighton; Dr. Catts, of Victoria; Dr. Sydney Jones, of New South Wales; and Professor Norman Chevers, of Calcutta. The Congress was opened by Professor Stockvis, of Amsterdam University, and the Burgomaster of Amsterdam, who welcomed the members to the Dutch capital. The inaugural address was delivered by Professor Stockvis, after which the Congress proceeded to its more special work under different sections, and at night the Burgomaster entertained the members at a brilliant reception at the Town Hall.

On Thursday, the question of Quarantine was under discussion, when Professor Vandencorput, of Brussels, suggested that there should be an International organisation for the systematic record of observations upon epidemic outbreaks and an International Association for concerting measures which would render quarantine unnecessary. Sir Joseph Fayrer and Dr. Ewart both spoke on the treatment of diseases introduced from tropical climes in countries of the temperate zone; while Dr. Scriven reported the result of the latest experiments in the injection of quinine as a remedy for malarial fever.

The propriety of holding annually an International Medical Congress to deal with hygienic questions specially affecting countries and colonies in the tropical portions of the globe was also mooted. Sir Joseph Fayrer, whose long experience in British India enabled him to speak with the highest authority, declared that, in his opinion, the colonisation of the plains of tropical countries by Europeans would never succeed. After three generations European families always died out. Even in the hilly districts of the tropics it was doubtful whether pure European blood could permanently perpetuate itself. Dr. Lewis stated that the children of English soldiers in India who were brought up in the hills from five thousand to seven thousand feet above the sea level were always more or less unhealthy and weak in constitution, though if they were sent to Europe in time they might generally lay the foundations of robust health.

The business of the sections was concluded on Friday, after which, at a general meeting, the question of the foundation of a special school for the training of physicians for the Colonies in tropical countries was discussed. The proposal of Professor Vandencorput for the establishment of an International Association to deal with the problem of epidemics was referred to the Special Committee for further inquiry, with instruction to report the result to the next Congress, which will be held in the Hague twelve months hence. The principal members of this Commission are Professors Vandencorput, De Chaumont, Lewis, Leroy, De Méricourt, and Da Selva Amado.

The proceedings of the Congress finally concluded on Saturday by a trip *en masse* to the charming seaside resort of Scheveningen, and a banquet in the great hall of the Cursaal there.

The Queen has, it is notified in last week's official *Gazette*, been pleased to grant unto Surgeon-Major Francis Bramley Baker, Grenadier Guards, late Senior Medical Officer of the Brigade of Guards in Egypt, Her Majesty's Royal license and permission that he may accept and wear the Insignia of the Third class of the Order of the Medjidieh, which the Khedive of Egypt has been pleased to confer upon him in recognition of his services during the recent operations in that country.

We understand that the Home Secretary has remitted three years of the sentence of five years' penal servitude passed upon Dr. Story, at the Bedfordshire Winter Assizes of 1881, for setting fire to his house at Linslade, with intent, as alleged, to defraud the West of England Fire Assurance Company. At the trial, evidence was called to prove that the prisoner, who was sixty-eight years of age, had suffered from sunstroke, and was subject to fits of temporary insanity. Dr. Story will be released next month.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 20, Bombay 38, Madras 30, Paris 24, Geneva 17, Brussels 22, Amsterdam 23, Rotterdam 23, The Hague 17, Copenhagen 23, Stockholm 21, Christiania 18, St. Petersburg 28, Berlin 28, Hamburg (State) 20, Dresden 25, Breslau 35, Munich 38, Vienna 22, Prague 31, Buda-Pesth 29, Trieste 26, Rome 24, Turin 28, Venice 24, Lisbon 33, New York 32, Brooklyn 29, Philadelphia 24, Baltimore 22.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 12, 1883.

IRISH PRISON SURGEONS AND THEIR GRIEVANCES.

THE Royal Commission to inquire into the management of Irish prisons is about to recommence its sittings, and will shortly, we believe, examine some of the medical officers. The investigation would be incomplete without a searching inquiry into the grievances of these officers, and the defects alleged to exist in the provisions for the care of sick prisoners. We trust, therefore, that as large a number as possible may be called, and the selection made representative, so that the well-grounded complaints of these officers, which have appeared in our columns from time to time, may be thoroughly sifted. That they should be is manifestly for the benefit of the public service. No department can work smoothly or well, in which the officers feel that they are suffering from injustice, and treated with harshness. This appears to be the case with regard to prison surgeons, and we have frequently been obliged to expose and comment, on what appears to us, the unwarrantable manner in which the Prisons' Board and Executive have treated them.

The duties of prison surgeons are defined in I. George iv. cap. 74, sec. 72, and 40 and 41 Vic. cap. 49, sec. 53. To the duties thus imposed others have been added by the Prisons' Board; and one of the complaints of the prison surgeons is, that although their pay was always inadequate, a very heavy addition has been made to their work, and no remuneration given therefor. That with duties analogous to, and quite as arduous and extensive, as that performed by the surgeons of English prisons, their pay is less. That either as the result of legislation for temporary emergencies, or to meet exigencies of the Prison Service, excessive demands are made on their time, and increased responsibilities imposed, and yet although their entire time is not given to the Government Service, remuneration for the extra duty is always refused. Thus for the heavy work connected with the care of the "suspects" the Government declined to consider their claims; and medical officers of local prisons are put in charge of convicts without any additional pay.

The duties imposed by the Acts of Parliament are not only arduous and responsible, but such as would, without careful and judicious administration, lead to friction between the medical officers and the Executive. In fact, there is no part of the prison discipline with which the surgeon has not to deal. He has, as it were, to stand between the Executive and the prisoner, and while on the one hand it is his duty to see that the punishment of imprisonment and hard labour is not unduly mitigated, on the other he has to take care that neither the life of the prisoner shall be endangered, or health injured, either by the necessary conditions of prison life, or the infliction of special punishment for refractory conduct.

He has likewise to inspect and report on the condition of the prison, on its cleanliness, the quality of the provisions, the sufficiency or the reverse of clothing and bedding, and on "any cause which may affect the health of the prisoners," duties which obviously may lead to unpleasant complications with the other officers.

For the performance of these duties it is essential that the medical officers should be independent of the local officials, and that they should have the confidence and support of the Board.

Yet their well-founded complaint is that the Board has not given them its confidence, that it has assumed an aggressive position, and unduly interfered with, and hampered, them in the due discharge of their duties.

Thus to pass over secret instructions to the governors to report as to their visits, discourteous minutes and remarks on their reports, regulations have been adopted which are distinct efforts to prevent them exercising, according to their discretion, the duties imposed by statute. For instance, the prison dietaries are framed to give so much nourishment as shall maintain, under ordinary circumstances, an average prisoner in health. If he thinks it necessary the surgeon is bound to order extra diet. This power the Board cannot interfere with directly, but it has made the exercise of it punitive, by ordering that in such a case the prisoner shall be considered sick, shall be seen every day, his name entered on the continuous treatment book, all involving considerable extra work and trouble. It has interfered with the statutable power of the surgeon to call in additional medical assistance, and has left them without any provision whatever for the nursing and care of the sick.

The medical officers have no one on whose report of the condition or progress of a patient they can depend, or any guarantee that their orders will be efficiently or intelligently carried out. If a prisoner is not ill enough to be admitted to hospital, he is left in charge of his class warder, who, as best he may, must administer medicine, make poultices, apply stupes, &c., if he has time to do so with his ordinary duties to discharge. If a prisoner is admitted to hospital, if the case is a bad one, the Board, on application, will sanction the employment of a nurse, provided one can be obtained. If not, the prisoner must be left in charge of two others of his or her class, with an occasional visit from the warder on duty. As classification depends on sentence, the danger of the moral contamination of prisoners from such association is obvious, while on medical grounds the arrangement is most objectionable. Yet the Board have turned a deaf ear to all the remonstrances of the officers.

The Board have required medical officers to attend the families of warders residing outside the prison, although counsel has advised that such an order was *ultra vires;* and have enforced the gratuitous examination, for the Civil Service Commissioners, of candidates for the Prison Service, although until he has passed the Civil Service examination and produced a medical certificate the candidate cannot enter the Service.

In fact, the Prisons Board do not seem to have at all comprehended the position and duties of the medical officers, and instead of treating them with the confidence and consideration which they deserve, and the welfare of the Service demand, it has adopted a policy which has not only interfered with the efficiency of the department, but has caused the gravest discontent.

We do not presume to anticipate the decision of the Commission, or to pre-judge a case, still *sub judice.* But from an intimate acquaintance with our subject, we have no hesitation in expressing our opinion, that for the thorough efficiency of the Department, it is necessary that at least one member of the General Prisons Board and one member of the Inspecting Staff should be medical men.

No purely lay Board could possibly form a correct judgment on the medical and sanitary matters which crop up, while the powers of the medical officers, and their duty to interfere with discipline, or to recommend on subjects of health, sanitation, food, and management of the prisoner, are so extensive, and so interwoven with the entire system, that, in our opinion, it is absolutely essential that the Board should have the assistance of a medical member and a medical inspector.

We do not put forward an imaginary case when we say that any day a difference of opinion may arise between a governor and medical officer as to the fitness of a prisoner for hard labour or punishment, or the necessity of his removal to hospital. In such a case it is obvious that a lay member of the Board or Inspecting Staff, is quite as incapable of deciding the question as the governor, and that it would hardly conduce to the benefit of the service to call in an outsider to solve the point.

We have a very strong opinion that such appointment should be made from the ranks of the prison medical officers. We know that there are men in the service whose scientific attainments and administrative abilities fully qualify them for such offices, and whose promotion would add to the strength and efficiency of the Board.

Apart from our special interest in the welfare of the medical officers, we, as well as the public at large, are deeply concerned in the management of prisons.

The prevention of crime and reclamation of criminals is a question which vitally affects all classes of society; and because we are convinced that a most important part in this work devolves on the medical officers, we urge on the Commission a thorough and exhaustive examination of the grievances and proposals of the medical officers, and that we suggest the addition to the Board and Inspecting Staff, of medical men who have acquired a thorough knowlege of the peculiar nature, difficulties, and extent of prison work; in whom the medical officers can have confidence; who can consult with them; and through and by whom sanitary, hygienic, and professional recommendations can be explained to the Board, and carried into effect.

◆

PURPURA.

Among the subjects selected for special discussion at the late meeting of the British Medical Association at Liverpool, none probably was more intrinsically interesting, or debated with greater prospect of future advantage than that of purpura, which Dr. Stephen Mackenzie introduced by a paper styled by the chairman of the Medical Section, with characteristic justice, as complete and philosophical. That our knowledge of the affection denominated purpura is halting and unsatisfactory is sufficiently and freely admitted, and nothing has tended to illustrate the truth of this suspicion so much as the discussion initiated by Dr. Mackenzie. Beyond the fact that under certain circumstances a condition that is not inappropriately known among the people as "purples" is produced, that the characters of this disease may be manifested as complications of various other affections, that it may apparently be sometimes induced by the toxic influence of certain drugs, and that it occasionally imports the gravest possibilities, are mainly the facts mentally associated with the picture called up by the name itself. More than this has scarcely yet become a matter of general information in connection with it; and it is eminently hopeful in the way of future advance that the consideration of the whole question is at length placed upon a basis that, while being speculative, is at the same time essentially philosophical.

Dr. Mackenzie's primary proposition, to the effect that purpura is a *symptom,* is, we venture to affirm, destined to find a wider circle of adherents than assented to it when propounded in the arena of discussion at Liverpool. While the position to be assumed in this regard was subject to vagaries incident on changeful interpretations of verbal meanings, it was absolutely impossible to arrive at any definite conclusions; but by assigning to phenomena of universal observation a strictly limited meaning, as is now virtually done for the invariable attendants of purpura, it is at length possible to consider the relations of this affection in the light of scientific reason, and with the assistance of scientific discoveries. It has been due to the fevered haste of descriptive writers hurrying to *describe* that which is only imperfectly understood that most of the confusion surrounding many of the problems of medicine is due; it is only by approaching the solution of these problems afresh, and with a determination to bring to the task every resource of modern discovery that chaos can be successfully re-ordered and converted to system and precision. In the words of Dr. Dyce Duckworth, "it is better to confess ignorance than to be over-confident on the basis of an unsettled foundation."

That the basis of explanation of purpura has hitherto been an unsettled foundation is shown in the history of medicine; that we are about to approach its consideration with a legitimate chance of obtaining elucidation in connection with it, is a fair and justifiable belief; and we may assume further that a beginning at least has been made in the right direction. That there is a subtler connection than any hitherto recognised between the phenomena of purpura and constitutional peculiarities may be taken as certain; as also that it is irrational to look for complete explanations of these phenomena in the present deficient knowledge that is possessed in regard to the agencies which originate them. Perhaps, however, the most gratifying feature of later investigations is the tacit understanding of this connection evinced on the part of observers, foremost among whom are they who boldly make appeal to the facts of heredity and constitution for hints in carrying out their inquiries.

The varieties of purpura are better classified without reference to the merely physical appearances they present than when these are trusted to entirely as differentiating elements; and that arrangement proposed by Dr. Mackenzie embodies the twofold merit of simplicity and suggestion. He would collect the forms under the four heads of (1) vascular, (2) toxic, (3) mechanical, and (4) neurotic, a plan which is sufficiently logical and inclusive to embrace all the cases that usually present. It may, of course, be urged that every instance noted may be placed in the category of neuroses, inasmuch as the effects produced on the nervous system by toxic, mechanical, or (indirect) constitutional agency are in the end those which cause reaction on the vascular apparatus. But such a rigid demarcation of causes in place of simplifying would rather confuse the consideration of the question, so that a more liberal use of sub-classes is indicated at the expense of strict scientific precision of nomenclature. There is, however, a *bonâ fide* advance made by the acceptation of the formula which assigns to purpura the position of a symptom, and in the clear appreciation of the *rôle* played in its production by the complicated mechanism termed *diathesis*. Thanks to latter-day workers, to the catholic spirit of inquiry which unites in a common desire to know, the most speculative philosopher dreaming back into the ages of unknown ancestry and the most stubborn positivist steadily unravelling the knotted skeins of facts that claim his best attention, and to the daily enlarging field of vision swept by the eye of science, we of this age are rapidly approaching to such understanding of the causation of disease as could never have been imagined by our predecessors of but a few generations earlier. Nothing short of the true spirit of research could have worked the wonders already witnessed by living men of not extravagant age; and the same spirit is fortunately alive and grows increasingly restive in proportion as its conquests over ignorance attain to greater perfection.

In a minor degree the treatment of purpura must be made dependent upon the importance of its symptomatological character. The indications for remedial measures directed to the radical ailment will be completely understood only when we are able to associate each instance of purpura with the particular constitutional affection giving rise to it, and the nature of which it is fairly within our power to appreciate. Then, also, numberless connections of a puzzling kind that now arise to perplex every calculation, will cease to be provocative of failure in treatment; such, *e.g.*, as the tendency exhibited towards recurrence in the same individual, its obstinate resistance to restraint in those more serious cases of the hæmorrhagic description, and the baffling attacks of purpura sometimes met with, and of such evil augury, in fevers and diabetes.

It has already been suggested that purpura would form a suitable subject for attentive investigation; no common affection can be too insignificant to repay the bestowal of time and attention in the manner proposed; and no disease, if diligently and assiduously studied by many careful observers, will be found unremunerative of valuable information. But purpura is especially worthy of this extended inquiry, for it is so intimately, but as yet obscurely, related to *conditions* rather than to organs or systems, that nothing but advantage can accrue from its investigation.

◆

DUBLIN HOSPITALS.

THE Annual Report of the Board of Superintendence of the Dublin Hospitals was issued for the current year in the month of July, and during the session of Parliament—a change in the period of issue which greatly increases its value, and which makes it manifest that the Board and its secretary, Dr. Martin, are anxious to meet the public wish by the arrangements of their department It appears, indeed, from the Report that much of the delay in its issue which has heretofore occurred, and many of its imperfections, are due to the laziness and unbusiness-like habits of the persons whose duty it is to render the information from which the Report is compiled. The Board complains that "some of the hospital authorities seem to be determined to adhere to their former dilatory method," and states "that the late publication of the Report is due to the impossibility of getting the returns sooner. The chairman of our Board had to, in several cases, address three letters to the boards of the hospitals before we could get the returns furnished."

This neglect of duty—not to speak of courtesy—on the part of hospital officials is altogether indefensible, and, in our opinion, it deserves to be dealt with by the Board by a vigorous exercise of the *fortiter in re* rather than the *suaviter in modo* which has in vain been employed toward these functionaries. These hospitals are largely subsidised from the public fund, and we imagine that an intimation that if they did not comply with the request of the Board their default would be brought under the notice of the Treasury would at once remedy the fault of which the Board has had occasion to complain.

The introduction of the telephone system into hospitals is noticed approvingly, and the authorities of many of the hospitals have already shown their appreciation of the value of this method of intercommunication by using it to bring their surgeons within ear-call of the institutions.

According to the statistical tables published in the Report, the number of patients admitted into the whole of the subsidised Dublin hospitals during the year was 9,414, making the total under treatment 10,140, of whom 9,085 left the wards cured, relieved, or were dismissed for other causes.

The mortality was 4·6 per cent. on the cases estimated on the numbers who have been discharged, or who have died, or whose cases have consequently been treated to a termination. 816 patients remained under treatment in the wards in the present year. The total average daily number of beds occupied in all the hospitals throughout the year was 719·47. The time spent in hospital by each patient under treatment averaged 20·28 days.

The reports upon individual institutions present some points of interest. As regards the Westmoreland Lock Hospital, the Board has been informed that owing to the great prevalence of venereal disease amongst the troops composing the Dublin garrison, it has been suggested as a means of reducing this disease to increase the accommodation in this hospital, so as to render it more adequate to meet the demands made upon it. The War Department have proposed an offer (subject to the sanction of Parliament) which the Governors have accepted, of a supplemental grant of £250 a year for the maintenance of ten beds, and to pay a further sum of £25 per bed per annum on the condition of new wards being opened for twenty beds. The grant in all not to exceed £500. This would enable the Governors to treat continuously the number of eighty patients as a daily average. The time spent in hospital by each patient averaged thirty days, and the average daily number of beds occupied during the year was 67·49.

The report on Steevens's Hospital expresses regret that the ward allotted to venereal patients is in an unsatisfactory condition. As a great part of good nursing consists in preserving cleanliness, we naturally surmised that the patients do not receive due attention in this respect. No special nurse is attached to this ward. "In last Report we noticed with disapprobation the condition of this ward, and we regret that our suggestions have not since been carried out with regard to the appointment of a male attendant."

The state of the Meath Hospital is spoken of in favourable terms, and especial mention is made of the establishment of an observation ward, and of the new arrangement which allows a patient to take a bath and resume his own clothes after he leaves the hospital, thus obviating the danger of carrying infection to his home.

Cork Street Fever Hospital is reported to be "in a very satisfactory condition as regards the comforts of the patients and the internal working of the institution."

The Committee of the Convalescent Home for Infectious Diseases have recently placed over £900 at the disposal of the Governors for the purpose of remodelling the part of the institution which has been heretofore devoted to small-pox cases. A contract has been entered on which will render this building admirably suited to receive convalescent patients.

As regards the very heavy expenditure of the Cork Street Hospital (over £100 per bed), the Board explains that the number of cases under treatment during the past year was less than in preceding years, which renders the cost per bed much higher than in other hospitals. This expenditure is to be accounted for by the necessity of maintaining a staff and establishment in readiness for any sudden increase in the number of patients. It would be unsafe to the community at large not to have a considerable number of spare beds always available to meet the requirements made upon the hospital during the prevalence of epidemic diseases.

We are not entirely satisfied with this explanation, and venture to suggest that the Board might with great advantage inquire more minutely into the outlay in this institution. We doubt that any other instance will be found amongst the fever hospitals of the world in which it costs 15s. for officials and establishment to outlay 5s. for the benefit of the patient; and if it be true that, in order to be prepared for emergency, a staff is permanently maintained which is three times larger and more expensive than ordinary requirements of the public demand—which we greatly doubt—we think it the duty of the Board of Superintendence and of the hospital managers to make an effort to devise some more elastic and less exorbitant method of doing business. We fancy that a ready indication of the cause of the preposterous expense per bed of the Cork Street Fever Hospital would be found in its detailed accounts, and we shall certainly look for something more satisfying in the way of an explanation when the next Report of the Board comes to be issued.

The House of Industry Hospitals are, as regards their general condition and management, fully approved by the Board; but a correspondence between the Governors and the Castle is printed which makes it manifest that the building is hopelessly unfit for its purpose, and only worthy of being razed to the ground and rebuilt, and we trust that before this time next year an understanding will have been arrived at to replace these effete constructions by buildings worthier for their purpose.

The paragraphs in reference to the Rotunda and Coombe Lying-in Hospitals are altogether laudatory. In the Rotunda the mortality of the labour patients, deducting the 201 non-parturient cases, was 1·18 per cent., and that of the chronic class was 4·78 per cent. In the Coombe, deducting 38 non-parturients, the mortality was 2·18 per cent. for labour cases, and 4·68 for chronic cases. The expenditure of the Coombe Hospital is monstrous. Each bed occupied costs just £72, of which sum only £21 goes to the patient, while £50 is absorbed by officials and establishment. Comparing the outlay on this hospital with that of the sister institution—the Rotunda—we find that the establishment of the latter is only £39, and the total cost per bed £59. Considering that the Governors of the Coombe are suspected of an intention to provide for this extravagance of administration out of the pockets of the teaching staff, we feel ourselves entitled to ask for an explicit explanation of the exorbitant outlay of the institution. The Board of Superintendence seems to have asked in vain, for the Report says: "In our previous reports we have on several occasions adverted to the high cost per bed. The explanations of the Governors have not always been satisfactory; at the same time, it must be remembered that a great portion of expenditure is incurred by the dispensary department, in which most of the medicine purchased is given out." We do not believe that the outlay on medicines for externs has anything to say to the monstrous establishment charges of the Coombe Hospital, and we must certainly hold the Board of Superintendence responsible for a further and fuller inquiry, and some more satisfactory information on this subject.

We have pleasure in acknowledging the marked change for the better in the Report of the Board. It has now become a useful document, and we hope that the use we have made of it to criticise the financial administration of certain hospitals will not be without a result which, if attained, must be credited to the labours of Dr. Martin and his Board.

◆

Notes on Current Topics.

Epithelioma of Cervix Uteri—Recovery without Operation.

Cases of the above have been recorded from time to time, and upon perusing the reports of such cases carefully one can scarcely arrive at any other conclusion than that if actual recovery does not take place, such a degree of improvement does that we can scarcely blame the fortunate attendant for designating the result as recovery.

It has long been observed that under certain circumstances, such as high general pyrexia, as in the case under notice, erysipelatous inflammation around the affected part, other inflammations, such as that produced by the injection of irritants in the vicinity of the diseased portion (Duplouy), or like that produced by the actual cautery in the affected mass (Gallard), or around it (Nussbaum), a normal cell growth may, and occasionally does, take the place of the abnormal growth characteristic of cancer.

Such a case has been recently reported in the *Deutsche Med. Zeitung* by Dr. Staffhorst, of Ottendorff, Hanover. There appears to be no reason to doubt the accuracy of the diagnosis. The case was under observation several months; it resisted every method of treatment, the patient going almost steadily from bad to worse, and it was not till an unexplained attack of pyrexia, preceded by violent rigors, occurred, that any improvement took place. It might be supposed that the pyrexia was due to an attack of pelvic cellulitis, or peritonitis, and that this in some way modified the cell development of the diseased portion; but the report appears to negative this supposition. No mention is made of pelvic inflammation, and it is scarcely likely that such a complication should have remained undiscovered, or that no mention should have been made of it had any been noticed. Whatever the cause may have been, the progress of the disease seems to have been arrested immediately after the occurrence of the pyrexia: the hæmorrhages and offensive discharges ceased, and in the course of a few weeks the ulcerated surfaces were covered by cicatricial tissue. Some shortening of the vagina had taken place, posteriorly the cervix had become attached to the vagina, and some tenderness remained in the hypogastrium, especially after long standing. The patient's appetite was good, and she had increased in weight and strength, so that up to the date of the report, four months after cicatrisation, the improvement promised to be permanent. Upon the whole, we may conclude from the report of this case, taken in conjunction with expressions by other recent writers, that the prognosis in any particular case is not absolutely unfavourable, and it remains for us to follow up the faint glimmerings of hope that are here and there vouchsafed us.

Wandering Kidney.

In the *Charité-Annalen*, 1883, Professor Senator contributes an account of 32 cases. He proposes the name Ectopia renis as being more in accord with fact than the name at the head of this notice. According to him, ectopy of the kidney occurs once in every 139 women seeking advice, and that it is as common amongst the poorer as amongst the well-to-do classes. He considers the opposite conclusion, arrived at by some authors, to be based on insufficient or inexact data. He does not look upon the disappearance of fat as the cause of the abnormality. He considers the peculiarities of sexual life and of the clothing of women to be predisposing causes. Of 42 cases observed by Landau, 40 had borne children, whilst of 27 of Senator's, 22 were mothers; the writer therefore looks upon repeated pregnancies and the consequent softening of the abdominal walls as factors in the production of the affection. Displacements of the sexual organs, hydronephrosis, and tumours of the kidney are spoken of as possible causes. Tight lacing he looks upon as a sin that must be held responsible for its share in the production of the malady, and he considers the fact that the affection is more frequently right than left-sided as a justification of this accusation, as pressure is more likely to be continued through a solid organ, such as the liver, than through a space occupied only by the colon and the spleen, which is comparatively insignificant in point of size. As regards diagnosis, the only reliable sign he considers to be the discovery of the tumour, and he recommends as the most suitable position of the patient the supine, with the thighs passively raised. The position of the examining physician appears to be a matter of indifference, or rather habit, as he and Landau recommend different sides of the patient's body as best on which to make the examination.

Fever Generators.

It is perhaps too liberally conceded that sanitation, when carried out to the extent observed in large towns, where the influences of civilisation hold undisputed sway, is equal to successful contest with disease in all its forms; at any rate, Londoners, even, are occasionally reminded by serious outbreaks of contagious fevers in their midst, of the possibilities of danger lurking in the very centres they are accustomed to regard as safe from invasion; and such an experience as this has just recently brought home the truth of the reflection that immunity can be purchased at no cost less than absolute carefulness and constant attention. For some time past complaints have been made against the objectionably dangerous state of the Regent's Canal; and with a strange irony of comparison, the worst evidences of an unhygienic condition have been apparent in and about St. Mary's Hospital, where the stench from decomposing accumulations of filth exposed in the canal has been so bountifully disseminated as to evoke indignant protests at the supineness of the local authorities in permitting such a nuisance to exist at all. The amount of mischief possible to be created by an abomination of this description in such a neighbourhood is easily imagined, and offers a grave reflection on the absence of measures calculated to prevent the evil consequences that might be produced. Again, in the parish of St. Pancras, an outbreak of typhoid fever has been noticed, from the effects of which about thirty persons are known to have been sufferers, and the origin of which has been traced to milk supplied from a house where the first case arose. That an occurrence of this kind should be possible when the etiology of disease is so well understood as is true of typhoid, is, at least, unfortunate, and argues with irresistible force in favour of the adoption of a system of inspection which should be an efficient preventive of its future recurrence. Some time hence we may hope that incidents so destructive of a feeling of security in sanitary supervision will cease to disturb the householder's sense of protection; but until a much more complete plan of local and general hygiene is resorted to as a matter of course this desirable end is not likely to be attained; and meanwhile, we must continue to be subject to occasional ravages of epidemic ailments as the price paid for negligent sanitation.

The Social Science Association.

If the value of the work to be achieved at this year's meeting of the Social Science Association, which commences at Huddersfield on October 3, at all equals in importance the subjects to be discussed, there will be good reason for congratulating the members on their labours. The council of the Association have arranged for debates on a certain number of special questions, one of which, that of legislative enactments in the direction of amending the Sale of Poisons Act, is to be introduced by Mr. Meymott Tidy, M.B., Lecturer on Chemistry to the London Hospital. The discussion will turn on the need for and means of obtaining regulations preventive of employing purchased poisons with a criminal intent, and there is unfortunately too much reason at the present time why careful attention should be given to the problem. Dr. Clifford Allbutt, of Leeds, is announced to read a paper in the Health Section of the Congress on the question, "Is the modern system of education exerting any deleterious influence upon the health of the country?" a subject which has recently derived especial importance from the attention called to supposed evils arising from over-education. Several writers are down to communicate essays on the spread of zymotic diseases through the agency of milk supply, and the possibility of preventing the ills so arising in towns; and Dr. Norman Kerr will once more invite discussion on the Habitual Drunkards Act by suggesting the lines on which it requires amendment.

A Curious Cause of Death from Dyspnœa.

Occasionally there are met with in hospital and in private practice cases in which the only prominent symptom is dyspnœa, and the causation of which it is impossible to discover. Frequently such instances of difficult breathing are dependent on the growth of mediastinal tumours, malignant or otherwise; and at other times the active cause is aneurism, pressure on the trachea, or one or other bronchus being always the immediate cause of dyspnœa. In a case communicated to the Pathological Society of Philadelphia by Dr. Eskridge, and reported in the *Medical News*, the dyspnœic attacks were produced by a hæmatoma two inches long and one and a-half inches wide, found, *post mortem*, lying on the lower anterior surface of the trachea, embedded in connective tissue, and firmly held by old adhesions. It occupied a position just above and behind the transverse portion of the arch of the aorta. Three of the rings of the trachea, in the position where the greatest pressure was exerted by the semi-solid mass, presented a dark colour, and one of the spaces between the discoloured tracheal rings was nearly ulcerated through from the effects of pressure. The tumour consisted of more or less clotted blood, but no ruptured vessels or disease of any of the arteries was found. The calibre of the trachea was much reduced at the seat of the hæmorrhage. Dr. Eskridge explained the circumscribed position of the tumour to the presence of old adhesions between pleuræ and pericardium; but for them the blood must have gravitated downwards. The circumstances favouring its retention above would, however, favour also the rupture of small vessels, these latter being greatly stretched by the contracting tissue, and hence giving rise to the hæmatoma. The patient was a porter, accustomed to carry heavy weights, and difficult breathing first occurred after carrying an unusually heavy trunk for some distance. He lived some days in hospital, during which time several attacks of dyspnœa occurred, unrelieved by treatment, and he finally died during one of these paroxysms.

On Thursday afternoon, while two inmates of the Haddington District Lunatic Asylum, named Andrew Buchanan and Robert White, were in the lavatory, the former seized the latter by the throat, knocked him down, and while kneeling on his body, pounded his face with his fists in so dreadful a manner that he died in five minutes. White's face was so mutilated as to be hardly recognisable.

Copper and Cholera.

APROPOS of the controversy now raging respecting the prophylactic virtues of copper against cholera, Dr. F. A. Castle suggests, in a letter to the New York *Medical Record*, that copper workers enjoy the immunity ascribed to them by reason of their contact with mineral acids and acid salts, necessitated by the nature of their employment. Dr. Castle quotes Surgeon McClellan, of the United States army, to the effect that sulphate of iron and dilute sulphuric acid are prophylactic against cholera, and asks, "if we accept this opinion respecting the value of sulphuric acid as a preventive of cholera, is it not easier to account for the immunity of copper workers, who use it almost constantly in their art, than to presume that the metal itself affords the protection?"

The Death of Marwood.

WHATEVER criminal braggadocio may assert and large-eared credulity receive, there can be no question that Marwood died from natural causes; for lobar pneumonia with degeneration of the liver and kidneys is just a pathological condition which cannot possibly be mistaken for the effects of any poison or combination of poisons, vegetable or mineral. Had he died of apoplexy or angina pectoris or dysentery, or any one of a score of other diseases that might be named, there might have been room for the speculation that he had fallen a victim to the secret practices of those who have felt aggrieved by his professional conduct and have threatened his life; but, as it is, it is certain that his death has been neither violent nor untimely, but after the ordinary visitation of men. The degenerative changes in the liver and kidneys revealed by the autopsy must have been going on for some time, and may perhaps by their effects on his general health explain the want of coolness, nerve, and calculation which have been perceptible in some of his recent performances. The stories which we now read of Marwood's artistic conception of his work and of his secret of the long drop, which has died with him, are more than apocryphal; they are transparent nonsense. Greed, a love of notoriety, and a large share of that mawkish taste for the hideous and the horrible which keeps the *Police News* going, were doubtless the motives which led him to take up his gentle craft, and he hanged away by a crude rule of thumb which was often at fault in its application. His death will, it is to be hoped, call the attention of the Home Secretary to the whole question of capital punishment, and lead to its infliction henceforth in a more humane way than we have been accustomed to. Meanwhile, there is something akin to humiliation in the consciousness that the death of Marwood the common hangman is a matter, if not of national interest, at any rate of national concern. So long as the state of society is such that death penalties are necessarily enacted by retributive justice, so long must we retain the services of the Calcrafts and Marwoods *et hoc genus omne* as active agents for carrying out the requirements of the law. Optimists, however, would fain hope that by-and-by the hangman will no longer be a necessary element in the national life; and this not by reason of his place being taken by a more effectual and scientific destroyer of life, but because the instincts of inhumanity bred in the breasts of murderers will cease to find development. Be that as it may, the present must needs take care of itself, and unquestionably the hangman or his equivalent is still an essential safeguard to society. But in the embarrassment created by Marwood's somewhat sudden decease it may very well be considered whether his successor may not be chosen with a due regard to decency and good feeling, so that the peculiarities indulged in by Marwood may be less obtrusively imposed on public attention. The hangman's office need not necessarily entail individual disgrace, but nevertheless popular prejudice is opposed to surrounding it with any but unlovely circumstances; and, popular prejudices being long-lived and irresistible, it might well be made incumbent on the State executioner to abstain from parading the nature of his calling offensively in the intervals when he is not officially engaged. The interests of public morality, and indirectly, of public health, would be alike conserved by such a proceeding, the advisability of which may be commended to those who will be called upon to make a fresh appointment in the place of the dead official.

The Metropolitan Asylums Board and Cholera.

THIS very energetic and useful public body has sent a letter to the secretary of each of the London hospitals, stating that, with the view of carrying out the intentions of the Legislature with regard to the Diseases Prevention (Metropolis) Act, 1883, the managers desire to enter into negotiations with the several metropolitan hospitals, and to ascertain from them whether, in the event of emergency arising, they would be willing to place at the disposal of the Board a certain number of beds for the treatment of patients suffering from cholera. By the general adoption of such a course the managers anticipate that the expense of providing and maintaining a large number of special cholera hospitals may to a great extent be obviated. The letter points out that the whole of the expenses incurred incidental to the treatment of cholera patients in hospitals would be defrayed by the managers out of the Metropolitan Common Poor Fund. A similar letter has also been addressed to the several metropolitan boards of guardians having detached infirmaries, or other suitable places, under their control. As we are not desirous of prejudicing the course which the councils of the several institutions concerned may feel disposed to take in this matter, we shall defer our comments until the replies have been received by the Asylums Board.

Retiring-rooms for Females.

WE are glad to learn that the first of the proposed retiring-rooms for women whose duties or inclinations lead them to spend any length of time in and about the streets of London is now opened at 114 Gray's Inn Road. There is no charge made to those who make use of the convenience, but a box for voluntary contributions is placed in the building. Efforts are being steadily made to raise funds for the supply of similar retiring-rooms in all the principal thoroughfares, and the object in view is so eminently praiseworthy that we trust the movement may be completely successful.

The Marshall Street School, Edinburgh.

In a recent number of the *Medical Press and Circular* our readers were informed that the Marshall Street School of Medicine had come to an untimely end, this being the construction put by our Edinburgh correspondent on the announcement contained in the *Scotsman* of August 24 to the following effect:—

"Notice.—In reference to Mr. Urquhart's notice of the 22nd inst., I think it fair to the public to explain that, instead of my receiving dismissal, I, along with ten out of eleven of the medical officers, including all the consultants, resigned all connection with the dispensary and school in Marshall Street.

"Ths. W. Drinkwater."

We have received from Mr. Urquhart, secretary to the said school, a somewhat peremptory demand by telegram for the withdrawal of our correspondent's statement, and, being unwilling to be the cause of disseminating error, we are glad to explain, as shown above, that, though deprived of almost its entire staff, the Marshall Street School is still *in esse*.

British Pharmaceutical Conference.

The British Pharmaceutical Conference is this year to hold its annual meeting in Southport, under the presidency of Professor Attfield, F.R.S., on Tuesday, the 18th, and Wednesday, the 19th inst., in the Assembly Rooms of the Prince of Wales Hotel. An opportunity will be afforded to members on Wednesday to inspect the works of the Glaciarium, and a demonstration of Gamgee's process of making the ice will be made. The members will visit St. Helen's on Thursday, and permission has been obtained for the inspection at St. Helen's of the Union Plate Glass Works, the Copper Smelting Works of Messrs. Bibby, and the Chemical Works of Messrs. Kurtz. The return journey will be made in time for members to be present at a garden party to be held in the Botanical Gardens, Churchtown. Amongst the papers promised are the following:—Report on Tincture of Nux Vomica, by R. Dunstan, F.C.S.; The Preservation of Medicinal Herbs by Ensilage, by Professor Quinlan; The Pharmaceutical Aspects of the Mullein Plant, by Professor Quinlan; Aconitine for Internal Exhibition, by T. B. Groves, F.C.S.; Suggestions for Combinations of Collodion, by J. B. Barnes, F.C.S.; Sweet Spirit of Nitre, by A. C. Abraham; and, Does Cod-liver Oil contain Iodine, by E. Stanford, F.C.S.

How Small-Pox is Spread.

An outbreak of small-pox, introduced from Birmingham, has just occurred at Leicester, and has already resulted in one death. A young woman, working at Leicester, went to Birmingham to visit her mother, who is engaged as a nurse at the Small-pox Hospital there. The mother gave her daughter a dress which she had worn while nursing. The daughter took the dress to her home at Leicester and began to unpick it, but before she had completed her task she became ill, and was found to be suffering from a serious attack of small-pox. She was removed to the Leicester Small-pox Hospital, where she died. On Saturday two other cases of small-pox broke out in the house where the deceased girl lived. As a precautionary measure, to prevent the further spread of the disease, all the inmates of the house were induced to go into quarantine at the Small-pox Hospital, where they will be well provided with necessaries and amusements for fourteen days.

The medical staff recently sent out from England by Her Majesty's Government to Egypt will, with the exception of three, return home on the 17th inst.

London has been particularly free from fatal cases of summer diarrhœa this season, notwithstanding the great heat of the last three weeks in August. Last week the mortality from this cause only reached 1·0 per 1,000 of its population. During the same period it was somewhat excessive in the following large cities:—New York Brooklyn, Berlin, St. Petersburgh, and Paris.

The annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Halifax, Norwich 13; Bristol 15; London, Derby, Hull 17; Edinburgh, Oldham, Bradford 18; Sunderland 19; Leeds, Blackburn, Wolverhampton, Cardiff, Huddersfield 20; Nottingham, Birkenhead, Birmingham, Bolton 21; Portsmouth 22; Dublin 23; Liverpool, Salford 24; Plymouth, Sheffield 25; Brighton 26; Leicester, Glasgow, Preston 27; Manchester 28; Newcastle-on-Tyne 29.

We regret to announce the sudden death of Dr. William Goodfellow Laidlaw, of Birkenhead. Deceased attended to his professional duties as usual on Friday last, and on Saturday morning he was found dead, lying across his bed, having previously dressed, gone out, and returned. Deceased, who held the M.D. and M.B. degrees of the University of Glasgow, was forty years of age, was a native of Kilmarnock, and held two appointments under the Birkenhead Guardians. The inquest will probably reveal the fact whether death was due to suicide or to natural causes. We hope the latter.

The highest annual death-rates from diseases of the zymotic class in the large towns last week, were from measles 1·6 in Salford, and 3·5 in Newcastle-upon-Tyne; from scarlet fever 1·8 in Leeds, and 1·9 in Sheffield; from "fever" 1·2 in Birkenhead, and 1·6 in Portsmouth; and from diarrhœa, 7·0 in Brighton, 7·7 in Leicester, and 9·0 in Preston. The death-rate from diarrhœa, which did not exceed 1·0 in London, averaged 3·7 in the provincial towns. The 30 deaths from diphtheria included 19 in London, and 5 in Glasgow. Small-pox caused 4 deaths in London, 2 in Birmingham, and 1 in Sunderland.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

Edinburgh.—Health of the City.—The mortality in Edinburgh for the week ending with Saturday, the 1st inst., was 73, and the death-rate 16 per 1,000. There were 18 deaths under 1 year, and 23 above 60 years, of which 5 were above 80 years. Diseases of the chest accounted for 20 deaths, and zymotic causes for 4, of which 2 were due to scarlatina, and 1 to measles; the intimations of these diseases were 6 and 42.

Vital Statistics for Scotland.—From the Registrar-General's official returns for the eight principal towns during the week ending with Saturday, September 1, we learn that the mortality was 22·1 per thousand of estimated population. This rate is 1·0 above that for the corresponding week of last year, and 1·0 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 13·6 per thousand; and the highest in Glasgow, viz., 26·9 per thousand. The mortality from the seven most familiar zymotic diseases was at the rate of 4·3 per thousand, or 0·9 above the rate for the previous week. Diarrhœa and whooping-cough were the most fatal epidemic diseases, the mortality therefrom being most marked in Glasgow. Acute diseases of the chest caused 59 deaths, or 8 less than in the previous week.

Bazaar for the Sick Children's Hospital, Aberdeen.—Arrangements have now been completed for the holding of a bazaar in aid of the funds of the Hospital for Sick Children, and the Princess Beatrice, as previously mentioned by us, has graciously consented to take part in the opening ceremony on Thursday, the 27th inst. The hospital was opened in September, 1877, with fourteen beds; but such was the pressure on the accommodation that the directors had to increase the number of beds as rapidly as their funds permitted. There are now thirty in the hospital, and these are always full, the number of patients for a long time past having never been less than 32. Additional space is urgently required, not only for the reception of patients, but for the proper carrying on of the work of the hospital; and the bazaar has been promoted to enable the directors to make an addition to the building. From £2,000 to £2,500 will be required to carry out the plans. The appeal made by the directors has been very heartily responded to, and there will be a grand display of goods at the fancy fair. The bazaar will be held in the music-hall on the 27th, 28th, and 29th instant.

Mortality in Glasgow.—The deaths in Glasgow for the week ending with Saturday, the 1st inst., were at the rate of 27 per 1,000 per annum, as compared with 25 in the preceding week, and 23, 21, and 23 in the corresponding weeks of 1882, 1881, and 1880.

The Old Infirmary Buildings, Edinburgh.—The Lord Provost's Committee of the Edinburgh Town Council had on the 5th inst. under consideration a proposition that, as a step towards the disposal of the old Infirmary property remaining in the hands of the Corporation, after providing the necessary fever hospital accommodation, the building should be pulled down and the ground cleared. It was ultimately agreed to remit to a sub-committee to consider what course should be taken in regard to the property as a whole, so that the council may be in a position to indicate what portion of the ground, if any, they may decide on keeping open, and for what purposes the area offered to the public will be available.

Correspondence.

POSITION IN LABOUR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In an original communication published by you in the number of Aug. 22nd, under the above title, and written and read by Dr. M'Donald at the British Medical Association, Liverpool, I find his deductions as to the value of the new position founded on a published 25 primiparous cases, and out of these 25 cases, 60 per cent. had ruptured perinæums, a simply awful percentage to contemplate. To begin with, out of 25 primiparous cases, to have 11 forceps, I should say alone shows undue haste, and the worst is, that out of these 11 cases none escaped rupture more or less. Of the 14 left to Nature, 10 only succeeded in the new position so well as to be delivered without injury.

Now I will take 25 cases of primiparous women delivered in the old position, and I find my books show only 2 cases of forceps instead of 11 (in one of these the patient was 42 years of age), and I am happy to add that neither was ruptured. In the remaining 23 cases one was ruptured, but not enough to require an operation afterwards. Now I think this 4 per cent. of accidents favourably contrasts with 60 per cent. shown above.

I am, &c.,
Edmund O. Day.

Royal Hospital for Children and Women,
Waterloo Road, London.

THE NEW ACT FOR THE PREVENTION OF THE SPREAD OF EPIDEMIC OR INFECTIOUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Will you permit me to correct an error into which you have inadvertently fallen in your issue of the 5th inst.

At p. 207 you say "the Bill introduced by the Government to make better provision for the prevention of outbreaks of formidable epidemic, endemic, or infectious diseases, &c." I beg to say the valuable Bill now passed into law for the United Kingdom was not introduced by the Government, but by Mr. E. D. Gray, M.P. Though endorsed by Mr. Brooks and myself, the entire credit of the measure is due to Mr. Gray. By inserting this you will oblige,

Yours faithfully,
Charles Dawson, M.P.,
Lord Mayor.

The Mansion House,
Sept. 6th, 1883.

MR. PARSON'S APPLIANCE FOR FRACTURED PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—It is not my duty as one outside the medical profession to discuss with Mr. Robert Jones the propriety or otherwise of acting on the novel suggestion in his letter of June 21, to transform saddlers and blacksmiths into assistant surgeons. I may, however, be excused if, having been the patient whose case was treated by Mr. Henry Parson by means of the appliance described in that gentleman's letter, which he designed and himself made for me, I remark that, in my humble opinion, Mr. Jones has, in several important particulars, misrepresented—unintentionally, of course—the statements in Mr. Parson's letter. I would in particular draw attention to what must, I presume, be deemed a vital point in estimating the relative value of Mr. Parson's appliance, and one which, curiously enough, Mr. Jones does not make the slightest reference to—viz., that the fracture for which his appliance was designed was the third to the same limb, and the second in the same part of the patella. Mr. Jones makes the following curious remark:—"Should the patient, however, not commence to walk until imperfect union has occurred, Mr. Parson urges that movement of the fractured ends will produce sufficient activity in the parts to complete the union." No such statement occurred in Mr. Parson's letter; no such theory animated his treatment of my case; nor, I apprehend, could any surgeon understanding his profession think for a moment of putting forward such an entirely ridiculous principle of treatment. I may state that Mr. Parson was not called in until the sixth day, and after I had travelled about 300 miles from abroad, a journey involving many changes of position. On the occasion of my first accident I went through the orthodox course of treatment, involving eight weeks in bed in one position, the subsequent use of crutches, &c. I may, therefore, without desiring to argue mere surgical points, be allowed to express my opinion that Mr. Parson's appliance, from its simplicity and efficiency in securing apposition conjoined with immobility, is perfect, and appears to obtain the results that formerly, I believe, were only looked for from the somewhat perilous, and, at all events, unpopular use of Malgaigne's hooks. How this appliance can be described as "a much older method of procedure" than another that Mr. Jones mentions I cannot understand, as it was made and applied for the first time to my own case just over a year ago.

Surely such an appliance ought not to be curtly dismissed, and by a medical man, on an imperfect representation of its character and principle, or the mind of the profession prejudiced against what would, I am convinced, be gladly welcomed by those who, like myself, may chance, and have the misfortune, to be the victims of a fractured patella.

I am, yours, &c.,

Guildford, Sept. 5, 1883. A. F. W.

P.S.—Having been from home travelling, I have only recently seen Mr. Jones's letter.

Literature.

TUBERCLE. (a)

In the course of 240 pages, illustrated by nearly as many engravings, Professor Hamilton furnishes us with a clear statement of his views. As he observes, many points in his book may excite adverse criticism, but we think that those who differ from him will admit the necessity of carefully weighing what he has to say. The book originates in a series of papers contributed to the *Practitioner*, in 1879-80, but is now presented in a complete form with such alterations as to bring the subject matter up to the present day. After expounding the pathology of bronchitis and its complications, the author passes to pneumonia and tubercle, endorsing largely Niemeyer and Virchow. The most interesting point to many readers will be the last consideration—viz., the tubercle bacillus. Prof. Hamilton repudiates the notice that this bacillus is the unique cause of phthisis. He is not prejudiced against such a mode of origin. Indeed, when the papers appeared first, he avowed that a ferment produced in a caseous mass is the probable means by which a tubercular eruption is originated. Koch's discovery, therefore, could not be otherwise than probable, and it is admitted that he has isolated a bacterium which, when inoculated into animals, is capable of producing an outbreak of tubercle. But this is all, and many of Koch's conclusions are pronounced misleading. Among the difficulties which the bacillus theory does not explain are the common facts in reference to meningitis and laryngeal phthisis. Cohnheim holding the inhalation theory, does not tell us why the bacilli do not always affect the larynx first, and we know that organ is usually only secondarily involved. He does indeed mention the old notion of the sputum causing this complication, but why does the bacillus first pass through it to the lungs? Diphtherial poison, when inhaled, settled in the fauces. Should not the bacilli also? As to meningitis again, it is suggested that the bacilli are inhaled into the nares, and thence make their way up to the base of the brain! If so, we may ask, with our author, "why do the nasal membranes and *dura mater* escape infection, while the *pia mater*, which is disconnected in its blood-supply, and otherwise from the skull and its membranes proper, is selected as the seat of the tubercle deposited?" Other difficulties are freely stated by our author who, before laying down his own views, thus concludes his objections to the new notions:—"It seems to me that in all this there is a want on the part of those who hold these doctrines, of clear reasoning. Because we find the same bacillus in a caseous mass, and in a miliary tubercle, are we therefore to conclude that they are alike, and that the bacillus is the cause of both? Such logic seems almost incomprehensible in men professing to have a scientific training. We might as well conclude that, because croton oil taken out of a glass bottle produced a pustular eruption when applied to the skin, therefore the croton oil was not only the cause of the eruption, but had also called into existence the glass bottle, and that both the glass bottle and the eruption were in their constitution alike." Thus is the gauntlet thrown down. In following Virchow and Niemeyer the practitioner will find himself in accord with Prof. Hamilton's pathology, and certainly will not fold his hands in the hopeless manner of some fatalistic physicians at the earliest appearance of phthisical symptoms. Perhaps for this reason, besides others, the more hopeful views may have sufficient attraction for many to induce them to thoroughly master the very interesting volume before us.

◆

FOSTER'S PHYSIOLOGY. (a)

How great a debt of gratitude to Dr. Foster has been incurred by English students of medicine it would perhaps be difficult to estimate; but that the reality of the burden is abundantly appreciated is shown by the rapidity with which successive editions of the "Text-book of Physiology" have been exhausted. The work, indeed, is universally accepted as the classical treatise on the subject, and its appearance has admittedly been largely productive of the improved position now held by physiology as compared with the condition of things in this connection a few years ago. A better proof, however, to the same effect is yielded by the fast diminishing frequency of the complaint formerly made—somewhat irreverently, it must be admitted—by the average medical student, to the effect that the "Text-book" was accessible only to those who had mastered the study of "Fosterese" as a preliminary linguistic exercise. Dr. Foster's precise and scientific diction is, however, invested with special clearness of its own which has successfully conquered the dislike originally experienced towards it by those who had not been prepared for such reading by previous scientific training. This it was which served to render the introduction of the work as the most usually adopted introduction to physiology by licence-seekers; and the extension of its perusal throughout their ranks is almost the healthiest sign we could obtain of the higher standard of latter-day education in the medical sciences.

The plan on which Foster's Physiology is written is sufficiently well known to make it unnecessary for any general sketch of the work in this place. The fourth edition, however, presents certain notable changes in arrangement and contents, of which brief mention may be made. Thus, the division of the text into large-print sections, dealing with the fundamental bases of physiology, and smaller-typed paragraphs devoted to an account of controversial views, has been abandoned in this edition, methods and apparatus being in it alone relegated to the distinction of place conferred by reduced typography. This change, however, is less important than the omission of those lengthy narratives of disputed views in relation to certain moot-points which found a place in preceding editions. By students preparing for higher University examinations this loss will be deplored; but the announcement made in the preface to the effect that Dr. Foster and his colleagues are engaged in producing a special treatise on these advanced parts of physiology will more than counterbalance the disappointment.

In its present form, the Text-book is a magnificent treatise on general physiology, and we may well be proud that such a work is the production of an English teacher. As an exposition of the facts and theories of the science, and of the experiemntal bases on which it reposes, it is unrivalled in the language; and we again assert that its acceptance by students is the best possible evidence of the growth of a sound scientific spirit among them.

◆

HOLMES' MEDICAL ESSAYS. (b)

Of the nature of *writing*, in the direction, that is, of composition, the productions of Oliver Wendell Holmes' pen obtain universal recognition as among the choicest ornaments of literature. Poet, philosopher, scientist, and physician, he is probably himself the most admirable example that could be cited of the class of men who, by devotion to the duties of life, and by cultivation of the opportunities it presents for improvement have won the frequent expression of unbounded admiration. In this volume there are collected together some of the most characteristic of the author's orations; it includes those delivered by him on different occasions at opening and closing school ceremonies at Harvard University, and others read at various societies. In all, nine subjects are treated, but one only, "The Contagiousness of Puerperal Fever," is directly technical in character. This, however, is a most pitiless and unanswerable refutation of the non-contagion theory against which it is mainly directed; and in it are to be discovered all that force of argument and picturesqueness of style for which the veteran author is widely known. In point of brilliancy it may be thought that the essay on "Homœopathy and its Kindred Delusions" is the most noticeable in the collection; certain it is that if it were to be generally read by adherents of "delusions" at the present time we might probably hear less even than is the case of the rampant quackery that parades unblushingly in our midst. Dr. Holmes is unsparing in his exposure of the utter foolishness of the system he condemns, and nothing finer or more convincing than his demonstration of the historical connection between various forms of humbug in medicine can be found in contemporary literatnre.

(a) "On the Pathology of Bronchitis, Catarrhal Pneumonia, Tubercle, and Allied Lesions of the Human Lung." By D. J. Hamilton, M.B., F.R.S.E., Professor of Pathology (Erasmus Wilson Chair), Aberdeen. London; Macmillan & Co. 1883.

(a) "A Text-book of Physiology." By Michael Foster, M.D., F.R.S. Fourth Edition. London: Macmillan and Co.

(b) "Medical Essays." By Oliver Wendell Holmes. London: Trübner and Co.

We could most earnestly desire that present day theorists on medical education would attentively read the address on "Scholastic and Medical Teaching" contained in this volume. Too surely is it to be feared we are drifting away from the clinical standpoint of medicine in favour of dogmatic teaching *ex cathedra*; and too surely likewise as this proceeds will practitioners grow to be less purely students of disease than students of opinion respecting disease. It would be the best possible thing that could happen if only this essay were to be read as the "opening address" at every medical school in the Kingdom next October.

Anything in the shape of actual criticism of these papers is out of the question. To disparage would be impossible; to praise would be presumption; we can only admire, and having read, regret that the volume is unique and that its author has not supplemented it with other similar reflections of his many sided genius.

◆

DR. G. BECK'S THERAPEUTICAL ALMANACK. (*a*)

This handy little pocket-book professes to give a short account of, or a reference to, all the recent changes that have taken place in therapeutics during the past year. We cannot show the success it has achieved better than by giving an extract taken at random. Let us take the subject of whooping-cough—

"℞ Pot. brom., grm. 2;
Sod. brom., grm. 4;
Am. brom., grm. 2;
Syr. chloral, grm. 50.

"M. ʒj to ℥ss in a glass of milk with the yolk of an egg. *Dujardin Beaumetz.—Journ. de Med. et de Chirurg. Prat.* 1882, p. 181.

"℞ Acid carbol., grm. j.;
Aq., grm. 50;
Syr. menth., grm. 40.

"M. Three to four tablespoonfuls a day. *Oltramare.—Allg. Med. Centralzeit.*, 1882, p. 292.

"℞ Acid carbol., 0·012-0·025 grm. for a dose in infancy. *Macdonald.—Virchow's Jahresbericht*, 1881, I., p. 464.

"℞ Quin. hydrochl. twice daily as many decigrammes as the child is years old, in aqueous solution; also tannate of quinia in double the dose. *Beckel.—Allg. Med Centralzeit*, 1882, p. 528.

"℞ Tinct. eucalypt, 3 grm.;
Glyc., syrup, aa grm. 15;
Aq., grm. 100.

"A dessertspoonful every three hours. *Witthoner.—Allg. Med. Centralzeit*, 1882, p. 1220.

Amyl nitrite, belladonna, aconite, benzoin, bromide of ammonium, carbolic acid, cerium oxide, chinoline, hyoscyamine, pilocarpine, ol. terebinth, salicylic acid, chloral, quinine, see 1882."

Then follows a reference to the general literature.

The above extract is a fair sample of what is to be found under the different headings.

The subjects are classified conveniently for reference. There are besides two copious indexes, the last of which alone would have been amply sufficient. The price is very moderate, 1·60 m. (about 1s. 7½d.) The language employed is so largely compounded of the Latin ordinarily met with in medical literature, that those who are not German scholars will have little difficulty in making themselves masters of the contents of the volume.

◆

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Orthopædic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Mark's, 2 p.m.

TUESDAY—Cancer Hospital, Brompton, 3 p.m.—Guy's, 1.30 p.m.—St. Mark's, 9 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Westminster, 2 p.m.—West London, 3 p.m.

WEDNESDAY—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopædic, 10 a.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Mary's, 1.30 p.m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 2 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 2.30 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—King's College, 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal South London Ophthalmic, 2 p.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomas's (Ophthalmic Department), 2 p.m.

SATURDAY—King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m., and 2 p.m.—Royal London Ophthalmic, 11 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Notices to Correspondents.

The Students' Number, 1883-84.—The annual educational number of this Journal will be published on Wednesday, September 19th. Deans, Registrars, and others connected with the various medical schools throughout the United Kingdom, will oblige by forwarding the latest prospectus and such other information as will assist the Editors in the compilation of this important number.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

WOOD-WOOL AS A SURGICAL DRESSING.

In reply to Dr. Johnson, Mr. Slater, Dr. Wilson, Mr. Green, Mr. Richardson, and Mr. Stuart, as to where the "wood-wool" dressing referred to in an article in our issue for August 29 is obtainable, we would mention that the only manufacturers known to us are P. Hartmann, Heidenheim, Würtemberg, Germany, whose name was mentioned in the article alluded to, and the affiliated firm of Hartmann and Kiesling, of Hohenelbe, Bohemia. Glass-wool has been in pretty general use on the Continent for some time past, and could no doubt be procured through the same firms. A letter addressed direct to Herrn P. Hartmann, Verbandstoff-Fabrik, Heidenheim, Würtemberg, Germany, in English, would doubtless receive attention; or the wood- and glass-wool could be procured through any good English firm if they were put into possession of the name and address of the German manufacturers. We would suggest the Maltine Manufacturing Co., as we notice they are extensive advertisers in the German papers, and as likely to have correspondents abroad.

ERGOT IN WHOOPING-COUGH.

To the Editor of the Medical Press and Circular.

Sir,—I have been trying above with considerable success, and should like to know the experience of any other of your readers who

---

(*a*) "Dr. G. Beck's Therapeutischer Almanack." 10 Jahrgrang, 1883. Des Taschenbuches der Neuesten Therapie. III. Baüdchen I. Heft. Bern: J. Dalp. Tenth year.

have been doing the same. The preparation I used was Hewlett's liq. ergotæ purif.
Yours obediently.
Battersea Park, S.W. A. Phillips Hills.

Death of an Attested Centenarian.—A man named David Mitchell, who had completed his 104th year, died on Sunday last in Lanchester (Durham) Workhouse. He had been ill for some time, but was hale and hearty up to a few months ago. Mitchell was born at Fettercairn, a small village at the base of the Grampian Hills. When 18 years old he was apprenticed as a seaman, and followed that vocation until 1840. He was captured by a French privateer, and was confined as prisoner at Valenciennes along with the late Lord Barrington, Sir Thomas Clavering, and others. We was of a sociable and cheerful disposition, and retained to the last the full possession of his faculties. For a long period he has been an inmate of the same workhouse, was abstemious in his habits, and enjoyed better health during the latter portion of his life that he did fifty years ago.

Dr. Rumbold (St. Louis).—Our exchange list is already so full that we regret we cannot extend it.

Dr. Sunter (Isleworth).—We hope to insert your communication in our first issue after the Students' Number.

Dr. Summers will receive a private note after the necessary inquiries have been made. Upon the face of it, assuming the correctness of your version, the gentleman concerned would appear to have committed an egregious blunder.

FISH *VERSUS* MEAT FOR PAUPERS.

At a weekly meeting of the Wrexham Board of Guardians, on Friday last, it was reported that the experiment of fish dinners for the inmates had been tried, and the majority of them were decidedly in favour of beef. Some of them said that after eating a fish dinner they felt hungry. It was thereupon resolved to abandon the fish, notwithstanding its smaller cost and consequent saving to the ratepayers.

Student.—We think the list may be taken as fairly representative; of course, it is almost impossible that it should be absolutely perfect, as new books and new editions are so continually superseding others. The text-books on anatomy and surgery mentioned by you are reliable.

Dr. Gardner.—Numerous forms of special food preparations for invalids are manufactured by Mr. Brand, of Little Stanhope Street, and may be absolutely depended upon for purity and strength. Hazeline may prove efficacious in the case you mention. It should be used as an embrocation.

THE IRISH MEDICAL DIRECTORY.

The issue of this book for the year 1884 is now in preparation. The editor earnestly requests the members of the profession in Ireland who have not already done so to return to him, without delay, the circulars already forwarded to them, in order that accuracy may be secured. If medical men would only consider the trouble and expense which the reissue of circulars involves, and the injury which a Directory sustains by the publication, year after year, of inaccuracies which are not remediable by any system of editing, they would not omit to take the infinitesimal trouble of returning their circulars. The editor especially solicits a note of any inaccuracy throughout the work which may be observed by readers.

Mr. George Stevens.—You will find all the particulars for which you ask in our special Students' Number, which will be issued on September 19.

Dubiens.—Dry cupping is an operation that can be very readily performed, and may occasionally be productive of benefit. Special glasses are not requisite: the employment of wine glasses even may be resorted to, the principal objection to them being that the thin lip may produce inconvenient pressure on the skin. A taper will serve the purpose of a torch quite as well as the regular instrument.

Nil Admirari.—We cannot admit your proposition. It is neither justified by the events, nor itself in good taste.

A Suburban Practitioner.—The consultant should not have paid a second visit to a patient about whom you had called him in consultation without your knowledge. We should like to know the name of the physician who has acted so, and to be convinced that you do not labour under any error in the matter.

Dr. Collier.—It is a rule in hospitals, or at any rate in all we know of, for certificates to be given, whenever requisite, by the staff, entirely without fee.

DR. MOUAT AND MR. SNELL "ON HOSPITAL CONSTRUCTION AND MANAGEMENT."

To the Editor of the Medical Press and Circular.

Sir,—In reading over the very kindly notice of the joint work of Mr. Snell and myself "On Hospitals," in your issue for August 15, I find an accidental error, which I think is deserving of correction.

The hospital of Mons. Tollet to which I referred was the military hospital at Bourges, an artillery station where there is a large cannon foundry. The hospital of St. Eloi, at Montpellier, is still in course of construction, and will probably not be ready for occupation for another couple of years. Kindly make known this to the reviewer and to your readers, and oblige,

Yours, &c.,
Local Government Board, Whitehall. F. J. Mouat, M.D.

F. A. P.—We cannot recommend you to "pin your faith" to any special theory of pathology of uterine disorders. The safest view is surely the broadest, and you will find the most intelligent authorities the first to admit this truism. The "mechanical" system is that which attributes all disordered conditions to the effects of displacement; the "phlogistic" (though this term is now very rarely employed) that which assigns to inflammation the *fons et origo*. You will be well repaid for the time expended if you make a careful study of the history of gynæcology.

Dr. Robertson.—Each hospital is understood to possess a special operating day or days every week, when those operations which can be with propriety fixed for any particular time are performed, with the object of enabling students to gather instruction from witnessing them. Urgent cases, of course, come under immediate treatment at every institution. Wednesday is the special day at the London Hospital, the hour 2 p.m.

Mr. Andrews.—There are numberless ways of combining the sulphate of magnesia to make a reliable and more or less non-repulsive mixture. We can recommend the following:—℞ Mag. sulph., ℥ss.; acid. sulph. aromat. ♏xv.; syrupi zingiberis, ʒj.; aq. chloroformi ad ℥j.

A Midland Doctor.—There is no place so beneficial to strumous cases as Margate, whither you will do wisely to send your patient. By communicating with one of the medical practitioners resident in the town you will have no difficulty in obtaining information as to boarding establishments. There are a great number of these places, and as a rule most excellently managed.

The Successful Candidates for the Army Medical Service.—We notice with much satisfaction that at the last competitive examination for appointments in the Army Medical Service, eight out of the twenty successful candidates were educated in Ireland, a fact which contrasts strongly with the circumstances to which we recently called attention, that at previous examinations, although a number of Irish candidates were successful in passing, scarcely one received an appointment.

◆

Vacancies.

Cavan County Infirmary.—Surgeon. Salary, £94. Applications by September 18.

East London Hospital for Children, Shadwell, E.—Resident Clinical Assistant. Applications by September 19.

Hospital for Women, Soho Square.—House Physician. Applications to the Secretary on or before September 20.

Kent County Ophthalmic Hospital.—House Surgeon.—Salary, £100. Applications to Canterbury by October 1.

Parish of Canisbay, Caithness.—Medical Officer. Applications to Peter Keith, Esq., Barrogill Castle by Wick, by September 19.

Parochial Board of Killean and Kilchenzie.—Medical Officer. Salary, £150. Applications to the Chairman of Board, Glencreggan, Kintyre, Argyllshire.

Sheffield General Infirmary.—House Surgeon. Salary, £120. Applications by September 20.

Sheffield Public Hospital and Dispensary.—Junior Assistant House Surgeon. Salary, £50. Applications by September 21.

St. Peter's Hospital for Stone and Urinary Diseases, Covent Garden London.—House Surgeon. Honorarium, 25 guineas, with board, &c. Applications to the Secretary on or before September 25.

Appointments

Bairstow, T., L.R.C.P. & L.R.C.S., Assistant Medical Officer to the Edinburgh Provident Dispensary.

Brunton, C. E., M.B. Cantab., M.R.C.S., Assistant Medical Officer to the County Lunatic Asylum, Colney Hatch.

Collins, W. J., M.D., B.S., B.Sc. Lond., M.R.C.S. Eng., Surgeon to the Western Ophthalmic Hospital.

Heuston, F. T., Lecturer on Anatomy in the Carmichael College of Medicine, Dublin.

O'Neill, P. L., Coroner for the Southern Division of the co Kildare.

Births.

Hallowes.—September 4, at 11 King Street, Maidstone, the wife of A. H. B. Hallowes, M.R.C.S. Eng., of a daughter.

Nixon.—September 3, at 2 Merrion Square North, Dublin, the wife of C. J. Nixon, M.B., of a son.

Marriages.

Maturin—Scot-Skirving.—September 3, at St. Giles's Cathedral, Edinburgh, Leslie Maturin, M.K.Q.C.P., of Newtown, to Leila, only daughter of Robert Scot-Skirving, of Drummond Place, Edinburgh.

Oldfield—Williams.—September 5, at St. Saviour's Church, Herne Hill Road, S.W., Frank Oldfield, L.R.C.P., of Boyson Road, S.E., to Eliza Angel (Lily), youngest daughter of E. W. Williams, Esq., of Bermondsey, S.E.

Parkes—Bayley.—September 5, at Palace Gardens Church, Kensington, W. E. Parkes, M.D., of Soho Hill, Birmingham, to Mary Constance, third daughter of J. Clowes Bayley, Esq., 26 Ladbroke Gardens

Deaths.

Callaway.—September 4, at 2 Courtnay Terrace, West Brighton, Mary Ann, widow of Thomas Callaway, F.R.C.S., of Blackheath, aged 80.

Hardy.—September 5, at Rock House, Pembrey, South Wales, Frederic Hardy, M.D., of Southport, aged 77.

Kearney.—September 4, at his residence, Gofton Hall, Finglas. Edward Barrett Kearney, Staff Assistant Surgeon (late 4th King's Own).

Lawlor.—August 28, at his residence, 8 Day Place, Tralee, William H. Lawlor, M.D., L.R.C.S.I., late Surgeon to the County Kerry Gaol and Infirmary.

Master.—September 3, Alfred Master, F.R.C.S., J.P., of Norwich, aged 67.

Merry.—September 4, at Marloes, Hemel Hempstead R. Rosier Merry, M.R.C.S., L.R.C.P.L., aged 48.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 19, 1883.

STUDENTS' NUMBER.

PREFATORY.

"Contrary to expectations expressed in the Student's Number of the *Medical Press and Circular* for 1881, we are no nearer solving the great problem of medical reform at this moment than we were twelve months ago." This, which formed the opening sentence of our special number, bearing date September 20, 1882, very exactly expresses the condition of affairs at the present time; but it remains to be added that the past few months have witnessed a strong effort to bring to pass that which has long been felt to be so desirable in the best interests of medicine. A "Medical Acts Amendment Bill" has in truth been drafted on the lines laid down in the Report of the Royal Commission appointed to inquire concerning existing abuses and the need for reform; it has been introduced into the House of Lords, and with sundry modifications passed the third reading in that Assembly; and has been once read in the House of Commons. It is now, however, sufficiently notorious that in the declining days of the Session the measure was finally shelved, owing, it must be said, to the unfortunate backwardness of interested corporations in assenting to clauses which were absolutely necessary to secure that the Bill shall be a reliable instrument, but, at the same time, calculated to limit the profitable exercise of the prerogatives such corporations enjoy under existing arrangements. It would be affectation to pretend that this fiasco is less than a misfortune; it would be unjustifiable, under all circumstances to entertain more than a hope that next Session will be more fruitful of results in this connection; but, nevertheless, it is impossible to conceal that the task we are now called upon to perform, that, namely, of presenting a conspectus of the regulations made familiar by frequent repetition, is very disappointing, inasmuch as it had been confidently anticipated that the passing of a new Act during the Parliamentary year 1882-83 would have necessitated substantial changes in the original programme submitted for the consideration of intending medical students.

MEDICINE AS A PROFESSION.

Each year about this time the prospect of medicine as a means of obtaining a livelihood becomes a question of concern to large numbers of young men and their parents and guardians, who are debating the best adapted profession for selection; and spite of all that is said and written on the subject, it still remains undoubtedly true that, through error or false judgment, very many who are unfitted to become successful practitioners make their way to hospitals as aspiring new students, and tend to swell the ranks of "living mistakes." How well it would be if all the physical, mental, and moral qualities necessary to the making of a sound physician and surgeon were carefully and intelligently considered by those whom we shall, in the next month, be called upon to welcome as new pupils! What an amount of future tribulation and unspoken regrets would be prevented if such considerations were permitted to have their legitimate bearing in deciding the momentous question destined to influence the whole future life of the many hundreds of young men now on the verge of becoming registered students of medicine! And how materially would the Profession be benefited if a certain indefinite, but none the less unqualified proportion of them should be led, at the outset of their studies, to perceive the hopeless nature of the task they are setting themselves, to the end that they may ultimately assume the responsibilities of practice!

We make these observations, ungracious though they appear to be, in no carping spirit of mere discontented criticism; but because we are, in common with every careful observer of the Profession as a whole, convinced of the unmistakable truth contained in the assertion that the Profession is "overstocked." But it is not, nor ever could be, overstocked with useful men, with men who possess the characteristic and essential qualities that fit a medical man to perform the duties of his calling; of these there are far too few to supply the demands existing for their services; and hence it is that empty places are too often filled by the incompetent many, who would have shone in usefulness had they but chosen another walk in life, but who, as doctors, are throughout existence ill-paid, because deserving little, unappreciated because undeserving of higher recognition—and disappointed practitioners. The exercise of a little forethought at the outset would have prevented misfortune; but too late the truth becomes apparent.

What is wanted to constitute a good medical man is a many sidedness of character that all young men leaving school or college do not possess. He should be endowed with an intelligent capacity that will enable him to grasp the principles that lie at the root of his studies, and to apply them when called upon to make experience with disease; and such capacity is incapable of being tested by means of a preliminary examination in arts alone, such as now forms the sole standard of fitness to which intending students are invited. Moreover, he should be physically strong enough to support the fatigu and strain that all but the most favoured practitioners are, for a time at least, compelled to undergo; and to this must be added that personal deportment for lack o which many otherwise excellently qualified men entirely fail to win the more solid rewards of professional work.

It is right and proper for every young student to hold before him as examples worthy of emulation those honoured lights of medicine who, by their attainments and their earnest services to mankind, have achieved the highest scientific and social eminence to which they can aspire. It is not too much to say that every man will meet his due if he preserve a steady consideration of right, and live up to the traditions that govern his relations with his brethren and the world. Should that position be one in which he can dispense power by and bye, he owes it to himself not less than to others to use this power for the professional well being; and equally, even though his lot be cast in humbler spheres, it will ever be his to frame his actions so that honour may be his own always. In medicine more than in any other profession there occur opportunities of doing good for its own sake. By accepting these occasions and rightfully employing them, not with a view to personal advantage merely, does he who utilises them exhibit the ennobling influences exerted over its followers by the highest of all human callings.

REGISTRATION.

There is but a single portal through which intending medical students can pass to the commencement of their special education for practical professional life. This is the Students' Register, kept by the General Council of Medical Education and Registration, the high authority in all matters pertaining to the instruction and qualification of medical men. This Council was created in 1858 with a view to maintaining order and dignity in the profession, and empowered to carry out this duty. Its mode of performing the work entrusted to it, however, has always been peculiar, and has mainly consisted of incessant additions, subtractions, multiplications, and distractions of the elementary examinations admitting to the register of students. At present every such student must, before registration, give evidence of having passed one or other of a large number of arts examinations, among them being all recognised University examinations, such as the local, the various degree examinations, the examinations of the College of Preceptors, &c., &c. Several of the qualifying bodies also hold a special preliminary, success at which equally admits to the Students' Register. Following registration the actual medical education commences, and may be pursued either at a hospital medical school, or for a time under a registered medical practitioner. No time spent in the study of those subjects on which future examinations for licences, &c., to practise are held, *before* registration is recognised as forming part of the minimum period over which the curriculum must extend, save in the case of physics, chemistry, pharmacy, and osteology, these being subjects on which attendance on lectures prior to registration is acknowledged.

THE CURRICULUM.

The life of the medical student is minutely marked out for him by the regulations of the licensing boards, which all agree in certain principal features. Thus, no student is admitted to final examination for a licence to practise until the termination of forty-five months spent in medical study, nor until he has succeeded in passing an examination in anatomy and physiology not earlier than the end of his second winter session as student. There is, likewise, general agreement as to the subjects of examination, these including all the principal branches of medical knowledge and practice, such as medicine, surgery, midwifery, materia medica, and therapeutics, pathology, medical jurisprudence, &c. Moreover, in order to ensure that the curriculum has been appropriately pursued, all candidates must procure evidence of having attended certain lectures and demonstrations in duly recognised schools of medicine, and of having obtained practical acquaintance with disease in the wards of general hospitals. Hence the consideration of the student's career naturally divides itself into two sections, one Education, the other Qualification. We shall consider it under each heading, giving an account first of the various educational institutions, and subsequently of those which confer licences, &c. to practise. For purposes of easy reference also the three divisions of the United Kingdom, England, Ireland, and Scotland, will be treated separately, and we shall conclude the number with a general chapter on the Services, &c.

STEPPING-STONES TO THE PROFESSION.

Adopting for the nonce the Darwinian theory of the "survival of the fittest," we desire to point out that the most competent students are, as a rule, the most successful practitioners. It is true that, in order to secure a large ordinary practice, a man must have *diplomacy*, and exercise a certain polite discretion; but a large *ordinary* practice is not the only aim of the ambitious student, or the "worthy scholar," as Fitche would call him. Our allusion to the "survival of the fittest" is here made with the desire to induce those who contemplate the study of medicine to make themselves the "fittest," so that they may "survive" in the great competitive struggle.

There are certain young men who ought *not* to think of entering upon the study of medicine. These, we need scarcely say, are those who seek a life of ease and inaction, and who have no inclination for work. The selfish cannot succeed in our profession, and a boy who, at school, cannot play fair, and evince a chivalrous disposition towards his playfellows, is unfit for medicine, in which such great demands are made upon charitable and philanthropic feeling. But not only should fitness be considered as a preliminary condition; it is essential that there should be taste and culture in the education of the student's observational faculties, and he should strive to school his hands and eyes to make the best use of whatever comes before him. To one who has had such preliminary training, the profession of medicine offers as wide and as good a field as any other, and to such the following pages will be a storehouse of information.

Partnerships in General Practice.—Many men, looking over the voluminous accounts of college curricula and university regulations, either for themselves or their sons may naturally draw a deep sigh over the work to be done or the money to be spent, and exclaim, "What then?"

Of course, the full and complete reply to this question would fill a volume or two; but we may briefly indicate what can and what cannot be done, *as a rule*. There are many exceptions, but we advise no one to think that he will escape the general rules which affect the mass of men.

First, there is private practice as a destiny and ultimatum. In Ireland and Scotland it is generally found that private practice worth having only exists in large towns; elsewhere in these two divisions, medical men live chiefly on their appointments. In England this is not so; the appointments are subordinate to the practice everywhere; the succession to a practice can be very generally secured by purchase; but this is not so in Ireland or Scotland. But in England there are practices which cannot be bought; no money will command the highest class of practice; it is a personal thing which attaches to a man, and cannot be transferred. Partnerships are regarded as safe introductions to practice; but apart from the notorious charges for partnership, we regard them as greatly over-estimated in value. In considering a sphere for practice, the first question is the adaptability of the purchaser to what he contemplates. A suitable man will, as a rule, succeed to any practice where he is favourably and systematically introduced to the patients by his predecessors; but no man will undertake to resign his appointments and introduce a successor without a *quid pro quo*. Unless, therefore, a man has capital, he should not think of purchasing a practice.

For a partnership a considerable amount of capital is absolutely necessary, for the following reasons:—1. A share in a partnership, if of any value, is not likely to be had for less than £1,000. 2. The junior partner has to live upon his own resources until the money *earned* in the practice after the date of his entry is paid, *i.e.*, until the first year's bills have gone out and been honoured by the patients.

Assistantships.—An assistantship is a capital discipline for any man. Such engagements are not what they used to be, the assistant in a medical practice being now treated as a gentleman.

Medical assistants may be divided into two classes—qualified and unqualified; but the salary which either will obtain is far more a question of actual experience than of the diploma which may be held in any given instance. The experience obtained by an assistant in England, even though unqualified, may be sufficient to enable him to obtain a far higher salary than many gentlemen of much higher qualifications, but who are without knowledge of English practice.

To act as "locum tenens" it is essential that previous experience of practice should have been obtained, a full knowledge of dispensing being absolutely necessary, dress and personal appearance going also a long way towards securing an engagement.

An assistantship "with a view to partnership" is a thing that people read and write of, but seldom see. Experience shows it to be a mistake on both sides. If the assistant has money, he had better not appear in the practice as subordinate; if he has not the probation will not, as a rule, assist him to get a share in the practice.

If, however, a successful student declines to enter private practice as purchaser or as assistant, he may enter the public services—Army, Navy, or Indian—through the open doors of competitive examinations.

Colonial and Ship Appointments.—There are certain appointments, however, which are obtained without difficulty which are often inquired about. The postal service to and between the West India Islands is an unhealthy service, but is not a bad one for men who can control themselves. The salary and perquisites are equal to about £200 a year, with board and lodging. If a man lives through a few years, and does not fall a victim to the many temptations which present themselves, he may ultimately get promotion into the Cape line, which is regarded as a very good service.

To the Peninsular and Oriental Steam Company it is almost impossible to obtain entrance except by the personal influence of the directors. The same may be said of other steam lines which are popular. We have known candidates to wait with their names put down for two years without being sent for.

Colonists forming a new district sometimes club together to secure the services of a surgeon, and pay into a bank in the colony a guarantee fund. Such appointments are placed in the hands of respectable medical agents who have representatives in the colony.

In conclusion, it may be stated that, whilst we have indicated generally the portals to success *after* the diploma has been obtained, we have no intention of ignoring the fact that men of decision of character, good antecedents, and high qualifications can and do secure distinguished positions in the profession, and occupy a large space in the eye of the world. But genius is the heritage of the few, and the great majority of men will do well to moderate their ambition, and seek to do their duty in the customary spheres of life in which many noble-hearted men have lived, worked, and died, leaving the world somewhat better than they found it.

England.

I.—EDUCATION.

The first point to be decided by the English student of medicine is which of the numerous schools in London and the provinces he will select as the scene of his pupilage. In determining the question thus raised a large proportion of new students will naturally be influenced by particular circumstances to choose particular centres of instruction. Thus, those whose friends or relatives have themselves been students will be led to attach themselves to hospitals already familiarised to them by name; others will be attracted by the comparative fame of members of the visiting and teaching staff of certain institutions; and yet others will be guided in their choice by that very fallacious criterion of importance, the percentage of examination successes. In most cases, however, it comes eventually to be chiefly a matter of selection between a provincial or a metropolitan hospital, and, as most young men beginning their career as medical students are necessarily compelled to dwell in lodgings, the differing expense of town as compared with provincial existence is too little to be very materially considered. It may, however, be said, apart from this, that where by attending a non-metropolitan school for a couple of years the advantages of frequent home-visiting among the pupil's own immediate friends can be enjoyed, it is wise to so arrange that these preliminary years shall not be passed in London.

At the present time anatomy and physiology are so well taught in the majority of non-metropolitan schools that London schools enjoy no superiority in this respect, and, if the comparative tables issued each year by the Royal College of Surgeons have any value at all, they demonstrate this fact very clearly indeed.

When, however, the purely professional work is entered on—the study of medicine and surgery—it must be admitted that London hospitals present opportunities which it is impossible for country institutions to offer, and at least one year of study should be passed at a great hospital by every student before qualification, or, if he can afford it, more than one. To those who aspire to hold resident appointments this course may seem unwise because of the restrictions which confine such appointments to perpetual pupils, but in such cases arrangements are possible by which the payment of half the composition fee at some places, or even less, confers the desired privilege.

COURSE OF STUDY.

The curriculum of study is practically the same for all students at all hospital schools, and is regulated by the requirements of examining boards. The first eighteen months is mainly spent in acquiring a knowledge of anatomy and physiology, with a view to passing the first professional examination in these subjects, and at the same time the subject of chemistry is taken up. During the winter session, particularly, assiduous attendance in the dissecting-room is enforced, and will be faithfully carried out by every student who is mindful of his own interests, while during the intervening summer he should make the most of the opportunities he will be afforded of being instructed in practical physiology and histology.

The commencement of the second winter is at many hospitals taken as the period at which attendance on lectures in medicine and surgery should commence; but we would strongly advise the *neglect* of such subjects until the primary is successfully put away, for until that is accomplished any distraction from the pursuit of the studies connected with it cannot but assist the chances of misfortune. Such knowledge, moreover, as may possibly be gained from the lectures which could be attended during the second winter in medicine and surgery will be as satisfactorily acquired during the summer, when the primary is over, by laying a foundation by reading for systematic attendance in the succeeding winter session. In the same way we would recommend avoidance of the wards for the same reason until after the first examination is passed, or the second in the case of those bodies which require three to be gone through by candidates for qualification under them.

FEES.

An unfortunate appearance of competition is afforded by the contrast of fees exacted at the various London hospitals. With the exception of four of these institutions, a composition fee of 125 guineas is charged to full pupils, who, for this same, obtain admission to all the lectures, demonstrations, and hospital practice required for the different examinations. The four hospitals whose scale is not thus arranged charge from 90 to 100 guineas for the same return, and it, of course, becomes a matter of considerable debate in many cases whether the saving of from 25 to 35 guineas on the whole cost of education to be effected by joining a cheap hospital may not be advisable. It cannot be disguised, however, that these more economically priced hospitals do not secure so desirable a class of students on the whole as those where the fees are higher, and it is impossible not to feel that this is mainly due to the reduction, which is eagerly availed of by the less desirable class of commencing students of medicine. In time this must affect these schools, to their detriment, by collecting at them, in overpowering proportions, men who are not always influenced in action by the motives which weigh most with persons of culture and refinement. Indeed, it is sincerely to be hoped that the existing differences in respect to fees may not long continue to exercise the ill-effect it is calculated to encourage.

Scholarships and Prizes, however, offer a means by which diligent students may materially assist their resources, and even obtain assistance sufficient to all but cover their total expenses while *in statu pupillari*. At most hospitals "entrance" scholarships, equivalent to the total "perpetual" fee, are awarded at the commencement of each winter session to new students; and in each year valuable money prizes and exhibitions worth from £5 to £50, or more, are regularly awarded after competition. Particulars relating to them will be found below.

LONDON SCHOOLS.

The Schools of Medicine in London are the following, the scholarships, prizes, students appointments, fees, &c., being set forth in connection with each place named :—

St. Bartholomew's Hospital.—*Appointments:* Four house-physicians and ten house-surgeons are appointed annually without fee; each except the five junior house-surgeons, is provided with rooms, and all receive a salary of £25. A resident midwifery assistant and an ophthalmic house-surgeon are appointed every six months; they are provided with rooms, and receive a salary of £25 per year. Two assistant chloroformists, salary £50 and £25 and rooms; in-patient clinical clerks; clerks and dressers to the assistant physicians.

Scholarships, etc.—There are two open scholarships in science, value 130*l.*, tenable for one year, and a Jeaffreson exhibition, value 50*l.*, tenable for two years; preliminary scientific exhibition, value 50*l.*, tenable for one year; three junior scholarships, of 50*l.*, 30*l.*, and 20*l.*, respectively; preliminary scientific scholarships, value 50*l.*; Treasurer's prize for practical anatomy; Foster prize for practical anatomy; senior scholarship, value 50*l.*, for anatomy, physiology, and chemistry; Wix prize; Hichens prize; Lawrence scholarship and gold medal, value 40 guineas for medicine, surgery, and midwifery; two Brackenbury scholarships of 30*l.* in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine.

Scale of Fees.—Fees for perpetual attendance on lectures and hospital practice, 132 guineas, payable in the following instalments: First winter, 40 guineas; first summer, 46 guineas; second winter, 46 guineas; or a single payment of 125 guineas. Fee for general subjects for students of dental surgery :—First winter, 31½ guineas; first summer, 31½ guineas; or a single payment of 63 guineas.

Charing Cross Hospital.—*Appointments:* Medical and surgical registrars, each with a salary of 40*l.* a year; resident medical officer, assistant medical officer, resident surgical officer, assistant surgical officer, resident obstetrical officer, assistant demonstrator, pathological assistant, clinical clerks and dressers. The resident officers are provided with rooms and commons, and the assistant officers with commons, in the hospital.

Scholarships, &c.—Two entrance scholarships of 30*l.* and

20*l.* respectively, tenable for one year; the Llewellyn scholarship of 26*l.*, open to all matriculated students who have completed their second year; Golding scholarship of 15*l.*, open to matriculated students who have completed their first year; the Pereira prize of 5*l.*; the Governor's clinical gold medal. Silver and bronze medals and certificates of honour are awarded to the most deserving candidates in the various classes.

Scale of Fees.—Composition fee for matriculated students 91*l.* 7s., payable in instalments of—First year's fees, 38*l.* 17s.; second year's fees, 36*l.* 15s.; third year's fees, 10*l.* 10s. Composition fee for the course of dental surgery, 42*l.* 2s. This school is now located in the complete and extensive new building erected for the purpose.

ST. GEORGE'S HOSPITAL.—*Appointments:* House physicians and house surgeons are elected half-yearly from among the perpetual pupils. They are entitled to hold their appointments for twelve months, and to board and reside in the hospital, free of all expense. Assistant house physician; assistant house surgeon; obstetric assistant with a yearly salary of 100*l.*, and board and residence in the hospital; pathological curator, with a salary of 50*l.*; microscopical pathologist, with a salary of 25*l.*; medical and surgical registrars, each with a salary of 50*l.* per annum; assistant medical registrars; assistant surgical registrars; ophthalmic registrar; ophthalmic assistant; demonstrator of anatomy, with a salary of 50*l.*; senior assistant demonstrator, with a salary of 20*l.*

Exhibitions, etc.—The Brown exhibitions, one of 100*l.* per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of 40*l*, per annum, tenable for two years, and open to students in their third year. The Brackenbury prizes: one each in medicine and surgery. The Clarke good conduct prize, the Thompson medal, value 32*l.* 5s 11½d., the Brodie clinical prize in surgery, the Acland clinical prize in medicine, the Johnson memorial prize in anatomy, the Treasurer's prize, and three general proficiency prizes of ten guineas each.

Scale of Fees.—Composition fee for perpetual pupils, 125*l.*, or in the following instalments: First year, 45*l.*; second year, 45*l.*; third year, 40*l.* For attendance on the hospital practice and lectures required by the examining corporations, 45*l.* for the first year, 45*l.* for the second year, and 20*l.* for each succeeding year. The latter scale of payment does not entitle the pupil to become house physician or house surgeon, or to compete for the Brown exhibitions. The fee for general subjects in dental surgery is 55*l.*, payable in two instalments: first year, 30*l.*; second year, 25*l.*

GUY'S HOSPITAL.—*Appointments:* Six house surgeons and house physicians, twelve obstetric residents, clinical assistants and dressers, are selected from the students, according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships, etc.—Open scholarship of 125 guineas, in classics, mathematics, and modern languages. Open scholarship of 125 guineas, in chemistry, physics, botany, and zoology. Six scholarships, varying in value from 10*l.* to 50*l.* each, for general proficiency in medical study, open to students of different years. The Joseph Hoare prizes; the Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery, the Gurney Hoare prize of 25*l.*, for clinical study; the Sands Cox scholarship of 15*l*, per annum for three years, for physiology and physics; the Michael Harris prize of 10*l.*, for anatomy.

Scale of Fees.—For the entire course of lectures and hospital practice, 125 guineas, if paid in one sum on entrance, or by two equal instalments of 66*l.*, payable at the commencement of the first winter, and of the following summer session; or payment may be made by instalments of 50*l.*, 50*l.*, and 37*l.* 10s., payable at the beginning of the first, second, and third years respectively. Fee for the dental course, 63 guineas, or in two annual instalments of 40 guineas and 23 guineas.

KING'S COLLEGE HOSPITAL.—*Appointments:* One physician's assistant, two house-surgeons, and one physician-accoucheur's assistant appointed every six months. They are supplied with board and residence in the hospital on payment of 30*l.* each. Assistant house-physician, assistant house-surgeon, and assistant resident accoucheur appointed every six months; in-patient clinical clerks and dressers; out-patient clinical clerks and dressers; obstetric clerks, ophthalmic, dental, and aural assistants; post-mortem clerks, assistant demonstrators and prosectors of anatomy.

Scholarships, etc.—Three Warneford scholarships, each of the value of 25*l.* per annum, two tenable for three years, and one tenable for two years; one Warneford scholarship of 25*l.* per annum, tenable for two years, open to resident students; three junior scholarships of 20*l.* each, tenable for one year, and open to students of the first year; one second year scholarship of 30*l.*, tenable for one year; and open to students of the second and third years, ; the senior scholarship of 40*l.*, tenable for two years, and open to students of the third and fourth years; Daniell scholarship of 20*l.* per annum, tenable for two years, for work in the chemical laboratory; two Sambrook scholarships of 60*l.* and 40*l.*; two Sambrook registrarships, each of 50*l.* per annum; two science exhibitions of 50*l.* and 25*l.*; two Warneford prizes of 25*l.* and 15*l.* respectively; Leathes prize; Todd medical clinical prize; Jelf medal; Tanner prize of 10*l.* for obstetrics. Class prizes, each of the value of 3*l.*, are awarded annually in particular subjects.

Scale of Fees.—Payment for the entire course of hospital practice and college lectures may be made in one sum, viz., 125*l.* on entrance, or by the following instalments:—70*l.* and 60*l.*, or 60*l.* on entrance, 50*l.* at the beginning of the second winter session, and 25*l.* at the beginning of the third winter session. Fees for the dental course, 95*l.* 1s. 6d.

LONDON HOSPITAL.—*Appointments:* The resident and other hospital appointments are free to full students. The resident appointments consist of five house-physiciancies, five house-surgeoncies, and one accoucheurship; also four dresserships and two maternity assistantships. All these officers are provided with board and lodging free of expense. There are also—non-resident—three clinical out-patient assistants, receiving 80*l.* per annum each; and two registrars, each with a salary of 100*l.*

Scholarships, etc.—Two entrance science scholarships, value £60 and £40, and two Buxton scholarships, value £30 and £20, will be offered for competition at the end of September to new students. A £20 scholarship for first year's students in anatomy and physiology. A scholarship, value £25, in anatomy, physiology, and chemistry, to first and second year's students; a scholarship, value £20, in clinical medicine; a scholarship, value £20, in clinical surgery; a scholarship, value £20, in clinical obstetrics; the Duckworth Nelson prize, value £10 (biennial), in clinical medicine and surgery; the Letheby prize of £30 for chemistry. Prizes, value £60 to dressers of out-patients, in minor surgery.

Scale of Fees.—Perpetual fee for lectures and hospital practice, and two years' practical anatomy, payable in three instalments of 45, 40, and 15 guineas, at the commencement of the first, second, and third yeers respectively, 100, or if in one payment, 90 guineas. Composision fee for students entering at or before the beginning of their second winter session, their first year having been spent elsewhere, payable in two instalments of 45 and 30 guineas, 75 guineas; or if in one payment, 70 guineas. Fee for lectures alone, 50 guineas; fee for hospital practice alone, 50 guineas; dental students (general hospital practice and lectures) 40 guineas; fee for dental practice, 10 guineas. Special advantages in the shape of reduced fees are offered to full students, who, having attended classes in natural science at other places, succeed within a certain time in passing the preliminary scientific examination. The composition fee covers four years' attendance only.

ST. MARY'S HOSPITAL.—*Appointments:* There are four resident medical officers, appointed for twelve months, and one, the obstetric officer, for six months; all of them live, free of every expense, in the hospital. Two paid prosectors appointed annually; two demonstrators of anatomy, receiving £70 and £50, and a resident registrar, appointed annually, and eligible for re-election. Clinical clerks and dressers. Demonstrator of pathological anatomy, £15.

Scholarships, &c.—Four scholarships in natural science, value £50 each; class scholarships of £20, £25, and £30, and prizes awarded at the end of each year, value £2 to £5, for proficiency in various subjects.

Scale of Fees.—For unlimited attendance on lectures and hospital practice, 125 guineas if paid by instalments, or 119 guineas if paid in one sum. Fee for hospital practice and lectures required by the examining bodies, 107 guineas in instalments, or 101 guineas in one sum. Fee for dental students, 62½ guineas.

MIDDLESEX HOSPITAL.—*Appointments:* Two house-surgeons, and six resident physician's assistants. The above officers have residence and board in the hospital free of expense, but they pay on appointment fees varying according to circumstances from 10 to 20 guineas. Clinical clerks and dressers.

Scholarships, &c.—One entrance science scholarship of £50; two Broderip scholarships of £30 and £20 per annum respectively, tenable for two years, for medicine and surgery; two entrance scholarships of £25 and £20 per annum respectively, tenable for two years; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21; clinical prize of £10 10s.; class prizes in particular subjects.

Scale of Fees.—General fee for the entire course of hospital practice and lectures, 90 guineas if paid in one sum on entrance, or by instalments of £40, £40, £20, and £5, payable at the commencement of the first, second, third, and fourth years respectively, Course of dental surgery, £42, or in two instalments of £30 and £15.

ST. THOMAS HOSPITAL.—*Appointments:* Two house-physicians, two house-surgeons, and one assistant for constant, a resident accoucheur, holding office for three or six months. The assistants are non-resident, but the other officers are provided with rooms and commons in the hospital free of expense. An ophthalmic clinical assistant, with salary of £50; surgical ward clerks, clinical clerks and dressers to in-patients and out-patients, obstetrical clerks, two hospital registrars, each with a salary of £100; assistants in the dissecting-room, prosectors, pathological assistants, and assistants in the physiological laboratory.

Scholarships, &c.—Two entrance scholarships in natural science of £100 and £60 respectively; for first year's students the William Tite scholarship of £30, and four college prizes, ranging in value from £10 to £20; for second year's students, the Musgrove scholarship of £42, and college prizes ranging in value from £10 to £20; for third year's students, three colleges prizes of £20, £15, £10, respectively. In addition there are awarded the Cheselden medal for surgery, the Mead medal for medicine, the Solly medal for reports of surgical cases, the Grainger testimonial prize of £20 for a physiological essay, and the Treasurer's gold medal for general proficiency.

Scale of Fees.—For the entire course of hospital practice and lectures, £123, paid on entrance, or £130 in two payments, £70 on entrance, and £60 at the beginning of the next year; or by three instalments of £60, £50, and £30, at the beginning of the first, second, and third years respectively. The fee for the attendance on the *general* subjects required of students in dental surgery is for the two years £55, or by instalments, £50 for the first year, and £10 for the second year.

UNIVERSITY COLLEGE HOSPITAL.—*Appointments:* Eight physicians' assistants, six house-surgeons, and four obstetric assistants are selected annually by examination from among the senior students without additional fee. They reside in the hospital, paying only for their board, and have charge of the resident patients in the absence of the physicians and surgeons. The offices of physicians' clerks, surgeons' dressers, surgical ward clerks, and ophthalmic surgeons' assistants are selected from among the pupils who are also students of the college, without additional fee.

Scholarships, &c.—Three entrance science exhibitions of £100, £60, and £40, respectively, tenable for two years; Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison scholarship, value about £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year, tenable for three years; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Dr. Fellows' clinical medal; the Liston gold medal; Alexander Bruce gold medal; Cruff memorial prize; class medals, &c.; gold and silver medals, or other prizes, as well as certificates of honour, are awarded, after competitive examinations in particular branches of study. Prizes to the value of £10 will be given in the class of hygiene. The Jews' commemoration scholarship of £15 for two years; the Tufnell scholarship of £100 for chemistry, two years; and the Clothworkers' exhibition of £50, for two years, can also be held in the Medical Faculty.

Scale of Fees.—125 guineas, if paid in one sum at the commencement of the course, or 130 guineas if paid by instalments, as follows: First year 60 guineas, second year 50 guineas, third year 20 guineas. Hospital practice and clinical instruction, perpetual, £36 15s.; one year, £15 15s.; six months, £10 10s. Practical pharmacy, three months, £5 5s.

WESTMINSTER HOSPITAL.—*Appointments:* Curator and pathologist, receiving £52 10s. per annum; medical surgical registrars, each £40; senior house physician and chloroformist, £21; junior house physician, house surgeon, and assistant surgeon, resident obstetric assistant. These officers, except the three first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—Entrance scholarships, in October. The Fence, £40 a year for two years, and one other, value £40, and two exhibitions of £20 each. Subjects—Latin, Mathematics, French or German, and Chemistry and Natural Philosophy. The Latin books are Ovid's Metamorphoses II., and Epistolæ exprits, I. There are also—an exhibition, value £10 10s. for first year's men; a scholarship in anatomy and physiology, value £21, for second year's men; prizes for clinical medicine and surgery of £5 each; the Frederic Bird medal and prize, value £15; the Chadwick prize for proficiency, value £21; and various class prizes.

Scale of Fees.—In one payment, £100; in two payments of 50 guineas each, payable on entrance and at the commencements of second year respectively, or by five payments distributed over five sessions, amounting to £115. There are no extras, except parts for dissection. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, £45.

SCHOOL OF MEDICINE FOR WOMEN.—The session at this school, which is situated at Henrietta Street, W.C., opens on the 1st October. Lectures are delivered during the usual educational session on all the subjects included in the medical curriculum, and there are available for the use of students a commodious dissecting room, physiological and chemical laboratories, and library, and numerous clinical lectures are regularly delivered at the Royal Free Hospital, Gray's Inn Road, which instruction is appropriated to the School for Women as a field of practical study and experience; clerkships, dresserships, and a pathological registrarship being tenable there without fee by lady students.

Scholarships, &c.—Entrance scholarship of £30. A scholarship of £50 for five years, to be competed for by ladies willing to prepare to become practitioners in India. £30 scholarship for three years to be competed for June 1884. £100 prize to be given shortly to a qualified lady physician who will study operative midwifery for one year abroad. Prizes and certificates awarded every session in all the classes.

Fees.—Tuition, evening instruction, &c., examination fees for L.K.Q.C.P.I. diplomas, £172 13s. For the Royal University of Ireland diplomas, £179 3s. For the London University M.B. and M.S. £18. Hospital practice only £45.

Medical students are admitted to the practice at the following metropolitan hospitals to which no medical schools is attached. More complete particulars will be supplied on application to the various secretaries.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and important hospital at the East End, containing 164 beds.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom; 192 beds, and in the new building, 137. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; perpetual, £5 5s.

HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W.; contains 21 beds; outposts, Newington Butts, Walworth, and St. John's Gardens, Notting Hill.—The practice of the hospital is open to students on payment: fee for three months' course, £3 3s.; for six months, £5 5s.; perpetual, £7 7s. Laryngoscopic demonstrations are given daily at half-past two.

CENTRAL LONDON THROAT HOSPITAL, Gray's Inn Road.—Twenty beds. Six clinical assistants, being either qualified practitioners or students of three years' standing, are elected to assist the surgeons. Fees for three months' attandance, £2 2s.; six months', £3 3s.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—The hospital treats above 6,000 out-patients annually, and makes up 40 beds.

Hospital for Sick Children, Great Ormond Street, Queen's Square, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, £3 3s.; perpetual, £5 5s. Secretary, Mr. Whitford. There are now 121 beds in the hospital, Great Ormond Street, and 52 beds in the country branch; total, 173. The practice at the hospital has been thrown open gratuitously to pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the secretary.

The Hospital for Women, Soho Square, W.—The hospital contains 61 beds. Clinical instruction is regularly given in the wards and in the out-patient room daily at 10 to members of the profession and to students after their third year. Clinical clerks and assistants are appointed from time to time. Application to be made to the physicians.

British Lying-in Hospital, Endell Street, St. Giles's.—Twenty-five beds. This institution receives women only as midwifery pupils. The fee for the course of three months is £10 10s. Pupils who prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

The Samaritan Free Hospital for Women and Children, Lower Seymour Street, W.—Fifty-two beds.

Royal London Ophthalmic Hospital, Bloomfield Street, Moorfields, is the largest of its class in the metropolis, and contains 100 beds.

London Fever Hospital, Islington.—260 beds.

Great Northern Hospital, Caledonian Road.

West London Hospital.—A well-appointed hospital at the western extremity of the metropolis, in the Hammersmith Road, recently enlarged, and containing 100 beds. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr. Gilbert, at the hospital.

Bethlem Hospital.—This hospital is open for the admission of two resident medical students who have recently obtained their diploma to practise medicine and surgery for the the acquisition of knowledge regarding the insane. The next election takes place in October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

Royal Free Hospital, Gray's Inn Road.—This hospital contains 150 beds. Of the smaller metropolitan hospitals few offer a more extensive field for students in medicine and surgery. At this hospital the students at the London School of Medicine for Women take out their medical and surgical practice. Clinical clerkships and surgical dresserships are held by these students. The fees payable are £20 the first, and £15 each succeeding year. *The School of Medicine* is situate away from the hospital. The composition fee for all classes and lectures, except clinical, is £80 in one sum, or three payments of £40, £30, and £15.

PROVINCIAL MEDICAL SCHOOLS.

Birmingham—Queen's College.—Students are admitted—(1) as matriculated students who enter for their entire medical education; (2) as occasional students for one or more courses of lectures; (3) as junior students, to prepare for the preliminary examinations of the licensing boards.

Scholarships, Prizes, etc.—The Sands Cox Prize, value 20*l.* Open to students who have completed their curriculum. Subjects:—Medicine, Surgery, and Midwifery. Two Ingleby scholarships for obstetric medicine and surgery and diseases of women, Sydenham and Queen's scholarships of 30*l.* The Warden's prize, value 5*l.* 5s., for first year's students, for general proficiency. The Percy prize, value 5*l.* 5s., for German.

Fees.—College fees for all lectures amount to 60 guineas, payable by two equal instalments.

Hospital practice is obtained at the General and Queen's Hospitals, which have been amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds, and the staff attached is of a very high order.

All students will be required to attend six months alternately at each hospital, as directed by the Clinical Board, excepting students who enter the hospital for six months only.

Clinical Prizes.—The following prizes are given annually: Senior medical prize for third and fourth year's students, first prize 5*l.* 5s.; second prize, 3*l.* 3s. Senior surgical prize for third and fourth year's students, first prize 5*l.* 5s.; second prize, 3*l.* 3s. Junior medical prize, for second year's students, first prize, 3*l.* 3s.; second prize, 2*l.* 2s. Junior surgical prize for second year's students, first prize, 3*l.* 8s.; second prize, 2*l.* 2s. Midwifery prize, 4*l.* Medals and certificates are awarded in each class. The examinations for all the appointments and prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, 42*l.*

Birmingham.—The Mason College.—The magnificent institution, founded, built, and endowed by the late Mr. Josiah Mason, and devoted to the spread of scientific information, is now open for the reception of students under a staff of eminent professors. Special facilities are offered at the college to intending medical students to complete the preliminary scientific work, without which they cannot hope to succeed in obtaining any one of the higher University degrees. Classes have been formed in chemistry, physics, biology, physiology, and practical work in all those subjects is carried out in well appointed and commodious laboratories. The fees for each course of lectures are payable in advance, and arranged on a scale of the most moderate kind, varying from half a guinea to three guineas for the whole. Further particulars will be found in the Calendar, to be obtained from the Secretary.

Bristol School of Medicine (University College).—Attached to this school, where there is ample provision for education and practice, are two well-appointed hospitals—the Royal Infirmary, containing 250 beds, and the General Hospital, with 154 beds. Competitive examinations are held amongst students of the first, second, and third years respectively, and prizes of money, instruments, and books are awarded annually. The certificates of this school are accepted by all the examining boards. Medical and surgical hospital practice and clinical lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional prizes are annually offered for competition amongst the students. The existing medical school is affiliated to University College, Bristol.

Scholarships, Prizes, etc.—Prizes and certificates of honour are given in the medical school to first, second, and third year's students, and also in practical anatomy. At the Royal Infirmary—Suple's medical prize, a gold medal and 7*l.* 7s.; Suple's surgical prize, as the medical; Clark prize (interest of 100*l.*) for third year's students; pathological prize, 3*l.* 3s. At the General Hospital: Martyn memorial scholarship, 20*l.*; Clarke scholarship (surgical), 15*l.*; Sander's scholarship (interest of 500*l.*), medicine and surgery; Lady Haberfield's prize (interest of 1,000*l.*), for general proficiency.

Clinical lectures are given at both institutions three and four times a week.

Fees.—School fees for unlimited attendance on all courses of lectures except comparative anatomy, 63*l.* For hospital practice, 35 guineas.

Leeds School of Medicine.—Clinical lectures are given by the physicians and surgeons attached to the General Infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the Infirmary by the surgeons in each department, where also are obtainable six clinical clerkships and eight dresserships. Besides the infirmary there is a large dispensary and a fever hospital, both of which are open to students of the school. Students at this school have excellent opportunities of acquiring a thorough insight of psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, and Dr. Major lectures on mental diseases during the summer. The systematic lectures are given at the school, and the clinical lectures at the asylum, which now accommodates 1,500 patients.

There is the Hardwicke scholarship in clinical medicine, value 10*l.*, the Thorp, in forensic medicine, value 10*l.*; three surgeons' clinical prizes, of 8*l.*, 5*l.*, and 3*l.* respectively. Silver and bronze medals, books, and certificates of honour are awarded for proficiency in particular subjects.

The composition fee for attendance upon all the required courses of school lectures is 50*l.* 8s., to be paid on entrance; or 27*l.* 6s. on entrance, and a second sum of 27*l.* 6s. twelve months afterwards.

At the General Infirmary the perpetual fee for medical practice and clinical lectures is 26*l.* 5s. The same amount is charged for the perpetual attendance on the surgical practice and clinical lectures. These fees are not included in the composition fees for lectures, and are payable separately.

University College, Liverpool (**Royal Infirmary School of Medicine**).—The infirmary attached to this school, which contains 300 beds, with 40 special beds for the treatment of diseases of women, offers admirable facilities to students for gaining practical knowledge.

A payment of 60 guineas on entrance, or in two equal instalments (one-half on entrance, and the remainder within twelve months) entitles the student to attendance on all the necessary lectures and demonstrations. The Royal Infirmary contains nearly 300 beds. There are special wards for the treatment of uterine and other diseases of women. The Lock Hospital, adjoining the infirmary, contains 60 beds.

Two house physicianships and three house surgeonships, tenable for six months, and open to pupils of the school who have obtained a legal qualification; clinical clerks and dressers; post-mortem clerks.

Two Roger Lyon Jones scholarships, each of 21*l.*, for two years, one awarded as an entrance scholarship, and the other being open to students who have completed their second year; the Torr gold medal for anatomy and physiology; the Bligh gold medal for anatomy and physiology. School medals and certificates of honour are awarded for proficiency in certain groups of subjects.

The fee for a perpetual ticket for hospital practice is 42*l.*, and may be paid in two equal instalments, one-half on entrance and the remainder within twelve months.

Manchester.—Victoria University, Owens College School of Medicine.—This school, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a faculty of science as well as of medicine, with departments of law and arts. Since the amalgamation a new medical school has been built on the most improved principles at the western extremity of the College Estate, and largely increased accommodation is afforded by extensive new buildings to be opened in October next. On the ground floor are two large lecture theatres, a library, and a museum. Over the lecture theatre is a dissecting-room, and over the library a physiological laboratory. The course of instruction afforded to students is thoroughly complete. Three of the most important chairs—those of anatomy, physiology, and chemistry—are held by professors who entirely devote their time to the work of instruction. Students wishing to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are offered for competition in this branch as an incentive to original research. The hospital practice is taken out at the Royal Infirmary, which contains 315 beds. The Monsall Fever Hospital and Cheadle Lunatic Asylum also afford teaching facilities of great importance.

Appointments.—Resident medical officer, Royal Infirmary, 250*l.* per annum; resident medical officer at Cheadle, 150*l.*; resident medical officer at Monsall, 200*l.*; resident surgical officer, 150*l.*; eight house surgeons, six months each; four house physicians, for six months each; a registrar; a pathological registrar—100*l.* each.

Scholarships, Prizes, etc.—Turner scholarship, 25*l.*, for third year's men; Platt physiological scholarship (two), 50*l.* each, two years; one annually for physiology. Platt exhibitions (two), 15*l.* each, for physiology. Dumville surgical prize, 20*l.*; examination in clinical surgery. Prizes of books, instruments, &c., varying from 5*l.* 5*s.* to 3*l.* 3*s.*, for third, second, and first year's students. Entrance scholarships: Dauntesey natural science scholarships.—Candidates, not to be over 25 years of age, may be registered, but must not have studied at any medical school; value about 100*l.*, for one year. Successful candidates must at once enter on full medical course in the Owens College. Examination takes place in October. Subjects: General and comparative anatomy, physiological botany, chemistry, including practical work, either mathematics or Latin. Gilchrist scholarships: Three of 50*l.*, for three years. One is annually awarded to candidates standing highest at matriculation of London University in June (provided he be in the honours division); failing such, two of 25*l.* to the two candidates standing highest in the first division; candidates must be between 16 and 20 years of age. There are also grammar school scholarships.

Fees.—Composition fee, 63*l.*, or two sums of 31*l.* 10*s.* each. Hospital practice: composition fee 42*l.*, or two instalments of 22*l.* each. Further information may be obtained of Professor Gamgee, Dean of the School, or of the Registrar, Owens College, Manchester.

Newcastle-on-Tyne College of Medicine.—This school is a department of the University of Durham, and contains ample provision for acquiring a sound education and practical experience at the bed-side. It is smaller than some of the provincial schools, but sound and successful teaching, attended with remarkably good examination results, are fast bringing it on a level with its competitors in point of numbers.

The Infirmary contains 230 beds. There are special wards for diseases of the eye, for lock cases, male and female, and for children. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital, which contains 12 beds. Opportunities for practical study are also afforded by the Dispensary, Fever Hospital, Eye Infirmary, Children's Hospital, and Coxlodge and Dunston Lunatic Asylums. Lectures are given on psychological medicine at the Coxlodge Lunatic Asylum by Mr. R. H. B. Wickham, Medical Superintendent. Mr. H. E. Armstrong lectures on public health.

Appointments.—An Assistant-Curator of the Museum is annually appointed from among the senior students, and receives £12 as an honorarium. Assistant demonstrators of anatomy, prosectors for the lectures on anatomy, assistant physiologists, pathological assistants, and assistants to the dental surgeon are also elected. Four times in the year two resident medical assistants, two resident surgical assistants, three non-resident clinical clerks, and sixteen non-resident dressers (eight for the in-patient, and eight for the out-patient department) are nominated by the Medical Board, and, if approved, appointed by the House Committee for three months. The medical and surgical assistants are provided with apartments and board in the Infirmary, on payment of £5 5*s.* for three months.

Scholarships, &c.—University scholarship, value £25 a year. for four years, for proficiency in Arts, awarded annually at beginning of winter session to perpetual students in their first year only. The Dickinson Memorial Scholarship, value £15 annually, for medicine, surgery, midwifery, and pathology; open to perpetual students who have passed the primary examination of a licensing body. The Tulloch Scholarship, interest of £400 annually, for anatomy, physiology, and chemistry. The Charlton Memorial Scholarship, interest of £700 annually, with Gold Medal, open to full students entered for the class of medicine at end of winter session. The Gibb Scholarship, interest of £500 annually, for pathology, at end of summer session. Goyder Memorial Scholarship in clinical medicine and clinical surgery, proceeds of £325 annually. At the end of each session, a Silver Medal and Certificates of Honour are awarded in each of the regular classes.

Fees.—Composition fee for lectures, £63, in one sum, or two instalments of £36 15*s.* each, or three instalments of £31 10*s.*, £20 5*s.*, and £21. Royal Infirmary perpetual fee, £26 5*s.*

Further information may be obtained from the Registrar, Dr. Luke Armstrong, Newcastle-on-Tyne.

Sheffield School of Medicine.—Students at this college obtain excellent instruction in medical and surgical practice at the General Infirmary, which contains 180 beds, and is provided with a museum and pathological and post-mortem theatres. The fees for perpetual attendance are £15 15*s.* for medical, and £21 for surgical practice; for twelve months' medical and surgical practice, each £10 10*s.*, and for six months, £6 6*s.* each. There is also the Sheffield Hospital and Dispensary, containing 104 beds, and is recognised by the College of Surgeons and the Hospital for Diseases of Women, to which students are admitted. The perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. Prizes to the value of £30, and certificates of honour, are given annually. Some of the lecturers, and other local members of the profession receive house pupils; such a mode of residence will be found far preferable to life in ordinary lodgings.

Liverpool Royal Southern Hospital.—This institution is one of the largest in the English provinces, and contains 200 beds. It has no school proper, although it contains accommodation for resident pupils, and clinical lectures are delivered daily by members of the staff. These, together with the practice obtained here, which is of a very varied and valuable character, are recognised by all the examining boards.

Inclusive fees: Perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately, on payment of half the above fees.

EXTRA-ACADEMICAL INSTITUTIONS.

London School of Dental Surgery.—This institution is the oldest of the dental colleges in the United

Kingdom, and its teaching is recognised by the Royal College of Surgeons for the dental diploma, (situated in Leicester Square). General fee for special lectures required for the curriculum, 15*l.* 15*s.* The Saunders Scholarship of 20*l.* per annum, and prizes, are open for competition. In connection with the above is the Dental Hospital of London. Fees for two years' hospital practice, 15*l.* 15*s.* Fees for lectures and practice, 31*l.* 10*s.*

National Dental College.—This is a more modern institution, it having been opened for teaching purposes about six years ago. In connection with the College is the National Dental Hospital, situate in Great Portland Street, which was established several years before the school. The teaching at this school also is recognised by the College of Surgeons for the dental diploma, and lectures and demonstrations are given similar to those at the other dental school. Fees.—General fee for special lectures required by the curriculum, 12*l.* 12*s.*; fee for the two years' hospital practice required by the curriculum, 12*l.* 12*s.* Total fee for the special lectures and hospital practice required by the curriculum, 25*l.* 4*s.*

School of Pharmacy of the Pharmaceutical Society of Great Britain.—Lectures are delivered on —(1) Physics in relation to chemistry and pharmacy; (2) Inorganic chemistry; (3) Organic chemistry, botany, and materia medica. These lectures are delivered on Thursday, Friday, and Saturday mornings, at nine o'clock. The laboratories are open from ten o'clock in the morning until five in the afternoon daily, except on Saturdays, when they are closed at two o'clock. Fee for ten months, according to hours of attendance, 12 to 25 guineas; for shorter terms in proportion. Each student is expected to attend every lecture of the course for which he has entered, or to state the cause of absence to the professor or to an assistant.

Cooke's School of Anatomy and Physiology—This is established for private tuition, and is situate close to University College, its principal being Mr. Thomas Cooke, F.R.C.S., Senior Assistant-Surgeon to the Westminster Hospital, whose private address is at 16 Woburn Place. The whole of the anatomy (on the dissected body), of physiology (with microscopical preparations, and such experiments as the law permits), and operative surgery (on the dead body), are gone through carefully every three months. Fees.— Anatomy and physiology, three months, 4 guineas; six months, 5 guineas. Special course for F.R.C.S., 5 guineas. Surgery—three months, 5 guineas; six months, 8 guineas. Special course for final F.R.C.S., 8 guineas. There is a well-appointed dissecting-room near the school.

South London School of Pharmacy—This school is situated at Kennington Cross, and is decidedly the most popular institution for the study of practical pharmacy and chemistry in London. It has accommodation for 120 students, instruction being also given in analytical chemistry for the purpose of qualifying gentlemen in search of appointments under the Public Health and Adulteration of Food Acts, by the principal, Dr. Muter. Lectures are delivered daily in the laboratory, and each student is required to practically illustrate the subject taught as the lecturer proceeds. The percentage of pupils passing at the examination is exceptionally high from this school. The winter session commences a fortnight earlier than that of the medical schools.

School of Homœopathy—Homœopathy has now a school of students, which is situate in Great Ormond Street, where lectures and instructions according to homœopathic principles are given by duly qualified members of the medical profession, and where students who believe in the *similia similibus curantur* theory can be taught according to their bent. The winter session at this school opens on October 1st.

◆

II.—QUALIFICATION.

There are in England seven examining bodies which confer qualifications to practice medicine. Four of these are Universities granting degrees; two are Colleges of Physicians and Surgeons respectively, granting registrable diplomas; the remaining institution is the Society of Apothecaries. The following account of these institutions includes particulars of the regulations under which the various qualifications are granted:—

THE ENGLISH UNIVERSITIES.

The distinction of a university degree carries with it so many advantages, social and professional, that every student who can possibly obtain so desirable a qualification will be consulting his best interests by straining every point in its favour. Of late years the facilities for obtaining the highest class degrees have so much increased, that an earnest and hard-working student not afraid of a good deal of extra labour, and with even average abilities, may readily gain for himself the distinguishing mark of culture conferred by graduation at one of the older seats of learning. The numerous scholarships open to general competition, and awarded at Oxford and Cambridge, &c., for proficiency in many of the subjects included in the preliminary medical curriculum, offer a ready means of meeting the extra expenses to be necessarily incurred at a university, as compared with the cost of ordinary qualification; and to this must be added the similar money prizes which, with only a slight additional labour, may be gained at the various hospital schools of medicine, and which will suffice to meet the major part of extra-academical outlay. Moreover, the liberal alterations introduced of late years into the regulations for the medical degrees of Durham University present a means whereby, with the sacrifice of less than twelve months of time spent "in residence" within the University bounds—and even this can be passed in regular medical study at the Newcastle-on-Tyne School of Medicine—any duly registered medical student can proceed to the examination for the M.B. degree of that University. On one point there is a common agreement among the universities, that, viz., they will admit no one to their earliest examinations who cannot show himself to have received a sound preliminary education in arts; and the necessity for this on the part of future medical practitioners is recognised no less now by all the examining boards of the Kingdom. Whatever the future ambition of the student, it will be wisest for him to be prepared with a view to ultimate graduation at a university, as thus will he be most effectively fitted to pursue the path leading to that goal, should opportunities arise for doing so. We will now briefly detail the principle features peculiar to the different universities in in respect of graduation at each.

Oxford.

Every student in medicine must pass all the examinations for the degree of B.A., and date the commencement of his medical studies from the final examination in arts or science. For the degree of B.M. two examinations must be passed, the first including Anatomy and Physiology (Human), Comparative Anatomy (chiefly the entozoa), and Physiology, Botany, Chemistry (theoretical and practical), and Physics, with Mechanics. All candidates, however, who have obtained honours in the School of Natural Science, or have passed the Honour examination in Chemistry, Mechanics, and Physics, are not required to offer these subjects again at the first M.B. At the second examination the candidate is examined in two of the ancient authors—Hippocrates, Aretæus, Galen, and Celsus—and in some one modern author, as Morgagni, Sydenham, or Boerhave, as well as in the Principles and

Practice of Medicine and Surgery, the Diseases of Women and Children, &c., &c. The first, or scientific examination may be passed immediately; and two years must elapse after passing the first, prior to the final examination for the same degree. A dissertation has to be publicly read three years after obtaining the M.B. before being eligible for the M.D. The medical examinations take place annually in Trinity Term.

Scholarships of value from 60*l.* to 100*l.* are obtainable at Christ Church, Magdalen, and other Colleges, by competitive examinations in natural science. Each year a Radcliffe Travelling Fellowship is competed for by those who, having taken a first-class at any of the public examinations of the University, or having obtained some University prize or scholarship open to general competition, propose to graduate in medicine. The Travelling Fellows receive 200*l.* a-year for three years, half this period being spent in study abroad.

During the past year a movement to utilise the clinical renown of the Radcliffe Infirmary for teaching purposes has been successfully inaugurated, and appointments have already been made with a view to giving effect to the intentions of reformers in this direction. Possibly Oxford may in time become what it is eminently fitted to be a successful and important School of Medicine.

Cambridge.

At the University of Cambridge, five years of medical study are required for the M.B., unless the student has graduated with honours as B.A., when four years suffice. He must have resided nine terms in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations for this degree. The first is in chemistry, physics, and botany; the second in anatomy (human and comparative), physiology, and pharmacy; and the third, in the usual practical subjects. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations, and an essay has to be written *extempore.* There is also a degree of Master in Surgery, for which the candidate has to attend extra courses of lectures on anatomy and surgery. An examination in so much of State Medicine as is required by medical officers of health will in future be held. The examination for certificates in sanitary science will begin on Tuesday, October 2. The names of candidates, who must be on the Medical Register of the United Kingdom, should be sent to Professor Liveing, Cambridge, on or before September 28. The yearly expenditure of a student who keeps his terms by residence in a college is from £150 to £200 a year. This however, may include all payments to the University and the college—all fees, as well as clothes, pocket-money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are very small. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

London.

The medical degree of London University is given to all and every one who succeds in satisfying the examiners of fitness to receive it. Women, as well as men, can proceed to it, irrespective of any consideration of residence or place of instruction, provided this has been obtained at a properly appointed hospital or hospitals.

Those students who intend to graduate at the London University should arrange their studies to pass the preliminary scientific examination *before commencing their regular medical studies,* taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained, which will go to clear the way for first year's studies, which would otherwise be much encumbered.

The preliminary scientific examination commences on the third Monday in July, and no candidate is admitted to it unless he has completed his seventeenth year, and has passed the matriculation examination. The subjects on which he will be examined are—Inorganic chemistry, experimental physics, botany, vegetable physiology, and zoology. Candidates who shall pass in all these subjects, and shall also pass at *the same time* in the pure mathematics of the first B.Sc. examination, or shall have previously passed the first B.A. examination, shall be considered as having passed the first B.Sc. examination also. There are in this, as in every other stage of the graduate's career, examination for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches, such as valuable scholarships, exhibitions, and prizes. The medical and scientific degrees of the University are—Bachelor and Doctor of Medicine, Bachelor and Master in Surgery, and Bachelor and Doctor of Science.

For the M.B. degree there are three professional examinations—namely, the preliminary scientific, the intermediate, and the final M.B. Before proceeding to the intermediate examination, which is held once a year, beginning on the last Monday in July, the candidate must have passed the preliminary scientific examination at least one year previously, and must produce certificates —1. Of having completed his nineteenth year; 2. Of having been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the following subjects: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine; 3. Of having dissected during two winter sessions; 4. Of having attended a course of Practical Chemistry; 5. Of having attended to Practical Pharmacy, and having acquired a practical knowledge of the preparation of medicines. Candidates are examined in Anatomy, Physiology and Histology, Materia Medica and Pharmaceutical Chemistry, Organic Chemistry. Candidates must show a competent knowledge in all the subjects. The examinations are conducted by printed papers and *vivâ voce* interrogation, by demonstration from preparations and specimens, and by dissections.

For the final or M.B. candidates must produce certificates—1. Of having passed the intermediate examination in medicine at least two years previously; 2. Of having subsequently attended a course of lectures on each of two of the subjects for which he had not presented certificates at the intermediate examination; 3. Of having conducted at least twenty labours; 4, and 5. Of having attended the surgical and medical practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on clinical surgery and clinical medicine; 6. Of having, after having attended surgical and medical hospital practice for at least twelve months subsequently to passing the intermediate examination in medicine, attended to practical medicine, surgery and midwifery, with special charge of patients, in a hospital, infirmary, dispensary, or parochial *union,* during six months, such attendance not to be counted as part of the hospital practice prescribed in 4 and 5; 7. Of having acquired proficiency in vaccination. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. Candidates are examined in General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The examinations include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. The examinations are conducted by printed papers and *vivâ voce* interrogations; by practical examinations in obstetric preparations and apparatus; by examination and report on cases of medical patients in the wards of a hospital; demonstrations from specimens and preparations. Candidates are expected to write prescriptions in Latin without abbreviations.

The regulations relating to the examination for honours, prizes, &c., and to the M.D. and B.S. examinations, may be obtained from the Registrar of the University, Burlington Gardens, W.

A special examination is held once in every year in subjects relating to public health, to which those candidates only are admitted who have passed the M.B. examination at least one year previously. Candidates will be examined in chemistry and microscopy, as regards the examination of air, water, and food; meteorology, geology, physics, and sanitary apparatus, vital statistics, hygiene, and sanitary laws, full particulars of which may be obtained from the Registrar.

All the medical degrees of the London University being open to women, valuable scholarships have been founded for their special benefit in connection with them.

University of Durham.

Two licences and three medical degrees are conferred by this University—viz., Licences in Medicine and Surgery, with degrees of Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. A certificate of proficiency in sanitary science is also awarded.

With regard to the degree of Bachelor of Medicine, no one will be admitted to that degree unless he has kept one year's residence at the Durham University College of Medicine, and in the case of non-university men an additional Arts examination to the professional examination must be passed.

Every candidate must be not less than twenty-one years of age, and must produce certificates of age, of registration as a student in medicine in the books of the General Medical Council, of good moral conduct, and of attendance on the usual lectures on hospital practice. In addition to the certificate of registration he must produce proof of having passed a somewhat higher Arts examination than those usually possessed before registration.

Candidates, however, who, at the commencement of their professional education passed the Arts examination for registration only, may pass in the extra subjects required either before or after presenting themselves for the first examination for the degree, but must do so before presenting themselves for the second examination.

There are two professional examinations, the first being held twice yearly, viz., in October and April, and the second twice yearly, in June and December. The subjects of the first examination are Anatomy, Physiology, Chemistry, Botany. The subjects of the second examination are Medicine, Surgery, Midwifery and Diseases of Women and Children, Pathology, Medical Jurisprudence, Materia Medica and Therapeutics, Public Health. The first examination will commence on Oct. 8th, 1883, and on April 21st, 1884. The second examination will commence on Dec. 3rd, 1883, and on June 23rd, 1884. The successful candidates for the first and second examinations for the degree of Bachelor in Medicine will be arranged in three classes—in the first and second (Honours), according to merit; and in the third (or Pass) in alphabetical order.

Candidates who have completed part of their curriculum elsewhere may pass their first examination *previously* to entering at Newcastle-upon-Tyne, and are recommended to commence their year of residence at Newcastle-upon-Tyne at the beginning of the winter session.

Full particulars relating to the M.D. (which is conferred under certain conditions without residence on Senior practitioners), B.S., and M.S. degrees may be obtained from the Registrar.

Royal College of Physicians of London.

Under the remodelled scheme of examination for the Licence of this College, which is a qualification to practise medicine, surgery, and midwifery, candidates are required to pass *three* examinations in all cases in which medical studies commenced subsequently to March 25, 1880. The *first* may be taken immediately after registration, and includes chemistry (with physics), materia medica, pharmacy, botany, and osteology. The *second* can be passed eighteen months after the first; subjects—anatomy and physiology. The *third* after forty-five months of study, and not until two years after the second. It includes anatomy, medical and surgical pathology, morbid anatomy, medicine and surgery, midwifery and diseases of women, forensic medicine, hygiene, and therapeutics.

Of the forty-five months of professional study, one winter and two summer sessions may be passed in either of the following ways: 1. Attending the practice of a hospital, infirmary, or other institution recognised by the College. 2. Receiving instruction as the pupil of a legally qualified practitioner, having opportunities of imparting a practical knowledge of medicine, surgery, or midwifery. 3. Attending lectures on any of the required subjects of professional study at any recognised place of instruction. Professional studies commenced *before* registration, except in the cases of chemistry, materia medica, botany, and pharmacy, will not be recognised.

Certificates required: First examination.—Evidence of having been registered as a medical student [by the General Medical Council: and of having received instruction in chemistry, including chemical physics (*i.e.*, heat, light, and electricity), in practical chemistry, in materia medica, in botany, and in practical pharmacy. (This examination includes osteology as well as] the subjects named.)

Second Examination.—Evidence of having passed the first examination; of having completed, after registration as a student, eighteen months of professional study at a recognised school or schools; and of instruction in anatomy and physiology.

Third Examination.—Evidence of being twenty-one years of age; of moral character; of having passed the second examination; of having been engaged in professional study not less than forty-five months; and of instruction in the remaining subjects of study mentioned in the tables, which will be supplied on application at the College.

The membership of the College is conferred after examination, which is conducted as follows:—Thursday: From 2 to 6, by written questions on medical anatomy, and on the principles of medicine. Friday: From 2 to 6, by written questions on the practice of medicine, including the principles of public health, and on psychological medicine. Saturday or Monday: The candidate's practical knowledge will be tested, either at the College, or in the medical wards of an hospital. Tuesday and Wednesday, by examination *vivâ voce.* This examination will commence on the last Thursday but one in January, April, July, and October.

Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British Colony, or who shall have obtained a foreign qualification entitling him to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study, and the examinations to be undergone previously to graduation, shall have been adjudged by the Censors' Board to be satisfactory, shall, if the Censors shall think fit, be admitted to the pass examination. The nature and extent of this examination shall, in the case of each candidate, be determined by the Censors' Board.

Under certain conditions the membership is to be obtained by practitioners over forty years of age without previously passing the examination for the licence, of which proof must be given by all other candidates except graduates in medicine as above described. But Licentiates admitted before February 16, 1859, and extra Licentiates otherwise may be admitted Members by a vote of the College.

The fees for the licence are £14 15s., and for the membership £31 10s.

Royal College of Surgeons of England.

The College of Surgeons requires every candidate for its Fellowship and Membership to pass two examinations, and in the case of candidates who commence their professional education on or after October 1st, 1883, proof must be adduced of having passed an examination in elementary anatomy and physiology conducted by their teachers at the several medical schools at least six months before their presenting themselves for the primary. Such candidates also will not be admitted to the second or pass examination until after the expiration of two years from the date of passing the primary, except under circumstances which are particularised thus:—

1. When a candidate, before presenting himself for the primary examination, shall possess a recognised degree or diploma in medicine or surgery, or shall have completed the curriculum of professional education for the diploma.
2. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the primary examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the primary examination for the Fellowship; it being required in such case that no less than one year of attendance on the surgical practice of a recognised hospital shall intervene between the date of his passing the primary examination for the Fellowship and the date of his presenting himself for the second or pass examination for the diploma of Member.
3. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance, shall fail to pass the primary examination at the end of his second winter session of attendance at a recognised medical school; provided that in his case not less than one year shall elapse between the date of his passing the primary examination and the date of his presenting himself for the second or pass examination for the diploma of Member.
4. When a candidate, owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the primary examination on the completion of his second year of professional study.
5. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the primary examination on the completion of his second year of professional study; it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

The regulations affecting "referred" candidates have also undergone recent amendments by which the conditions under which subsequent study must be pursued are more rigidly defined.

The second or pass examination includes a written, *viva voce*, and practical test in surgery, surgical anatomy, pathology, medicine and midwifery, but candidates can claim exemption from examination in medicine and midwifery under the following conditions, viz.:—

1. The production by the candidate of a degree, diploma, or licence in medicine and midwifery, entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in medicine or midwifery of a colonial or foreign University approved by the Council of the College.
2. A declaration by the candidate, prior to his admission to the final examination for Membership or Fellowship, that it is his intention to obtain either of the qualifications in medicine and midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

Candidates for the Fellowship must be twenty-five years of age, and must pass two examinations also, the primary, including comparative anatomy and physiology to some extent as well as human. The fee for the membership is £22, of which five guineas are paid before the final examination, on failure 3 guineas more before re-examination. Pass examination fee is five guineas at each presentation. Fellows—Total fee to members 15 guineas; to non-members, £31 10s.

The Apothecaries' Society of London.

Examinations are held every week during the year by the Apothecaries' Society, and licences are granted by it admitting to the practice of medicine in the United Kingdom, as well as certificates which entitle the holders to dispense medicines. A four years' course of study is required for the licence, and two examinations must be passed: the first, or primary, in anatomy, physiology and histology, chemistry, materia medica, and botany; the second, or final, in medicine, therapeutics, pathology, midwifery with diseases of women and children, forensic medicine and toxicology. Graduates in medicine of British Universities are admitted to a modified examination, which includes a clinical and practical test in medicine, pathology, and midwifery. Every candidate is examined practically and *viva voce* at both examinations, and in all the subjects; and is required to produce proof of attendance on the classes and lectures included in the full medical curriculum, surgery excepted. The fees payable are three guineas on entering for each examination, none of which is returned to rejected candidates. The fee for certificates to dispense is two guineas.

HOURS OF THE INTRODUCTOY LECTURES

To be delivered at the different Metropolitan Schools.

St. Bartholomew's Hospital: None. Session commences Oct. 1st.
Charing Cross Hospital: None. Session commences Oct. 1st.
St. George's Hospital: W. H. Bennett, Esq., Oct. 1st, at 4 p.m.
Guy's Hospital: None. Session commences Oct. 1st.
King's College Hospital: H. W. Acland, Esq., Oct, 2nd, at 4 p.m.
London Hospital: Prof. Huxley, Oct. 1st, at 8 p.m.
St. Mary's Hospital: Dr. Handfield Jones, Oct. 2nd, at 3.30 p.m.
Middlesex Hospital: A. Pearce Gould, Esq., Oct. 1st, at 3 p.m.
St. Thomas's Hospital: F. Le Gros Clark, Oct. 1st, at 3 p.m.
University College: Prof. John Tweedy, Oct. 1st, at 4 p.m.
Westminster Hospital: Boyce Barrow, Esq., Oct. 1st, at 3 p.m.

◆

Ireland.

I.—EDUCATION.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and, very seldom any other. In Dublin, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with the University), and a student of any hospital is free to enter at any school he pleases. In London, the student bargains with his hospiral and school—in the first instance—for a complete course of instruction, for which he pays—in whole or part—in advance, and his entire study is conducted within the one instution. In Dublin, on the contrary, the student enters for hospital and for courses of study separately, and takes the courses at any school he pleases which "gives best value." The teaching system—especially in Dublin—has recently entered on a new phase, by reason of the thorough and most necessary reforms contained in the new scheme of education and examination which the Irish College of Surgeons has decreed two years since. The future arrangement will be substantially as follows :—

1. The student will not be allowed, as heretofore, to defer his examination in general education until the eve of his final examination for his qualification to practise, but must pass his "preliminary," and register as a medical student not later than a fortnight from his commencing medical study.

2. The student will no longer be obliged or allowed to defer, as in times past, his first professional examination until the end of his third year of study. He will have to pass an examination at the end of each of his four years, and his course of education will thus be graduated from the elementary subjects to those more advanced and practical.

3. It will no longer be possible for the student to complete his course of study in a less period than three years and nine months, but the first of these years will be devoted to preliminary scientific studies, which *may* be worked at without coming to a medical school. No lecture or hospital attendances are *required* during this first year, but the student must prove that he has not been idle by passing an examination at its termination ; and, if he does not enter at a medical school, must satisfy the College that he has been *bona fide* pupil of a medical practitioner for at least nine months.

4. The payment of fees for lectures, &c, cannot any longer be deferred beyond one year, as the certificates of attendance *must* be produced for the examination which is to be passed at the end of that period.

5. The proofs of actual attendance at lecture and hospital will no longer be lax and unreliable, but will be stringently enforced.

These reforms will effect a most salutary change in the Irish medico-educational system.

COST OF EDUCATION IN IRELAND.

Should the student proceed on his own account, the lectures necessary for the diplomas of the Colleges of Physicians and Surgeons in Ireland will amount to about £75 ; hospital attendance, according to the new scale of fees, £36 ; lying-in hospital, from £4 4s. to £7 7s. These, with the diploma fees of £26 6s. for the College of Surgeons, and £15 15s. for the College of Physicians, represent the essentials, Thus, the absolute payment will amount to somewhere about £100, taking the minimum mode of payment. In addition to this sum are to be considered the payment for "grinding" or "coaching," by no means necessary to any industriously inclined student. The fixed sum is at present for private teaching usually £18 18s., *i.e.*, £9 9s. at commencement and £9 9s. after passing first half of the examination, for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary, say from £140 to £160 on a moderate scale.

This sum, or something like it, will secure to the pupi the advantage (?) of being "apprenticed" to a teacher, who will undertake all monetary responsibility for his education, and may be able to give him some special advantages as his own pupil at hospital, but the so-called apprenticeship is sometimes a simple contract for the payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice. Most of the apprentice holders will accept payment by instalments.

DATES OF ENTRY IN IRELAND.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the Session really does date from the 1st of November, and the entry of names may be delayed by the dilatory until the 15th of the same month.

The student begins work, attending hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and discussions. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

LECTURE ATTENDANCE IN IRELAND.

The system heretofore existing, under which a student could obtain unlimited certificates of "diligent" attendance on lectures and hospital in Ireland, though he might never have seen the inside of the lecture theatre, or be able to recognise the professor on meeting him in the street, has, been forbidden, and the issue of sham certificates is now confined to a few teachers and to those students who, being engaged in other avocations, cannot possibly study honestly and must, therefore, buy their sham certificates from the teachers who make the trade in these documents a matter of business. The Council of the Irish College of Surgeons has passed ordinances under which the actual number of lectures delivered and attended must be guaranteed not only by the teacher, but by the Registrar of the school, and by the student himself, who will be required to sign a declaration that if any statement made in his certificate turns out to be untrue, he will deliver up his diploma to be cancelled. The method of checking attendances at school and hospital has also been revised and made more stringent, so that evasion of the rules will be in future very hazardous, but there are still a few persons who are willing, for a consideration, to connive at the system of attendance by deputy and other fraudulent practices.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

The clinical hospitals of Dublin are ten in number, exclusive of the Cork Street Fever Hospital, two lying-in hospitals, two Ophthalmic hospitals, two Dental hospitals, the Children's Hospital in Pitt Street, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others, gaain, are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital and any school he wishes.

The Names of the Professors, Lecturers, and Hospital Staff of the following Hospitals and Schools are not included in this column, being found in the Advertisement of each Institution in another part of this Issue.

The School of Physic is a medical school formed by an amalgamation of the Schools of Trinity College and of the College of Physicians. The School is governed jointly by the Provost and Senior Fellows of Trinity College, and by the

President and Fellows of the College of Physicians, and is situated in the College Park. The Professors in the school are *ex officio* medical officers of the Sir Patrick Dun's Hospital. The Arts students of the University have certain advantages in attending at this School, but it is freely accessible to all students, and the instruction provided occupies a high rank. Every student of the school must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts courses unless he desire to obtain a licence or degree in medicine or surgery. No student is permitted to matriculate unless he has passed the first two years in Arts in Trinity College, in the preliminary examination of the Royal College of Surgeons in Ireland, or some other examination recognised by the General Medical Council. No student can be admitted for the Winter Courses after the 25th November.

Two Medical Scholarships are given annually in the School of Physic, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and institutes of medicine, comparative anatomy, chemistry, materia medica, botany, and experimental physics. Three-fourths of the lectures must be attended, and a daily roll is called by each Professor.

The Royal College of Surgeons' School of Surgery is attached by Charter to the Royal College of Surgeons, and has existed as a department of the College for nearly a century. It is carried on within the College buildings, and is specially subject to the supervision and control of the Collegiate Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued in the school. By the order of the Council, and with the sanction of the Fellows of the College, the School has been recently enlarged, reconstructed, and fitted with the most approved appliances. The anatomical department has been completely remodelled. The lighting and heating of the dissecting-room have received particular attention. A valuable series of permanent typical dissections have been placed in position round the room, in order that the student may be enabled to study the accurately displayed parts, and compare his own work therewith. A new laboratory has been constructed for the special accommodation of students in practical physiology. Each student is provided with a microscope, re-agents, and all other necessaries for making, staining, and mounting microscopic sections. He is, while so engaged, instructed in the minute anatomy of the tissues, and is enabled during the course to form and retain for his own use a complete cabinet of about one hundred typical specimens.

The Carmichael College of Medicine.—The school buildings are entirely new from their foundation, and the directors have provided all the most recent improvements, and to render every department fully adequate to the requirements of the most advanced teaching of medicine and surgery. The School is situated in immediate proximity to the Meath and Adelaide Hospitals, and is connected by its teachers not only with these hospitals, but also with the Richmond, Whitworth, and Hardwicke, the Rotunda, and the City of Dublin. The dissecting rooms and the physiological laboratory are spacious, well-ventilated, and admirably lighted, and are completely furnished with every requirement for the practical training of students in physiological and histological research. A bone-room, in which bones, anatomical preparations, &c., are kept, and a students' reading room, have been added to the accommodation of the School. Two scholarships, the "Mayne" and the "Carmichael," each value 15*l.*, and prizes to the value of 97*l.*, on the foundation of the late Mr. Carmichael, are offered annually.

The Ledwich School was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige. Its name was bestowed upon the school as a tribute of respect to the late T. H. Ledwich, who sacrificed a life in an unceasing effort to promote its welfare. It is situated in Peter Street, not five minutes walk from the College of Surgeons, the Meath, St. Vincent's, Coombe Lying-in Hospital, and Mercer's Hospital, and in the same street with the Adelaide Hospital, and the Carmichael Medical School, and ten minutes' walk from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

The Catholic University School is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. Most of its professors are physicians and surgeons of the Mater Misericordiæ, St. Vincent's, or Jervis Street Hospitals, and its courses of study qualify for admission to all the licensing bodies. The University itself does not grant degrees in medicine or surgery, being as yet unchartered, but the School is instrumental in the education of a large proportion of the Catholic students of Ireland. The University grants an Exhibition of 20*l.*, a gold medal, value 7*l.*, and class prizes.

The hospitals most closely connected with this School are St. Vincent's, in St. Stephen's Green; the Mater Misericordiæ Hospital, in Eccles Street; Jervis Street Hospital; and House of Industry Hospftal.

CLINICAL HOSPITALS.

Richmond, Whitworth, and Hardwicke Hospitals.—The accommodation of these Hospitals is as follows: Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. (They are Government Institutions and under the supervision of the Lord Lieutenant. These hospitals are visited each morning at 9 o'clock by the physicians and surgeons, and in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There is a very large ophthalmic and aural dispensary, and the respective surgeons give instruction in these important subjects. Eight resident clinical clerks and dressers are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students, as formerly, but also to those who are qualified in medicine or surgery. A house-surgeon for the Richmond Hospital is elected biennially, and receives a salary. The Richmond Lunatic Asylum, containing 1,000 beds, adjoins these hospitals.

City of Dublin Hospital is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. There are special wards for ophthalmic and aural diseases, on which subjects a special course of lectures is delivered. There is a special ward for diseases of women, and a course of lectures given on diseases peculiar to women; there is also a ward exclusively for children. The Drummond Wing is set apart for fever and other contagious diseases. Clinical assistants to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A house-surgeon is elected annually, and medical and surgical pupils are appointed by examination.

The Meath Hospital, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 127th year of its existence, ranks among the oldest of the charitable institutions of Dublin. It is situated on the southern side of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 10th October, 1570; this hospital was, in 1774, constituted the County Dublin Infirmary by Act of Parliament. The present building, in Heytesbury Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. 1852-53 the Collis Wards were added as a memorial to Maurice Collis, twenty-five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Woodhouse.

The Adelaide Medical and Surgical Hospitals are in Peter Street, next door to the Ledwich School, and within a few minutes' walk of the Carmichael Medical College, the College of Surgeons, and Trinity College. From the 1st of October the physicians and surgeons visit the wards, and give instruction at the bedside, at the advertised hours. There is a large detached fever hospital and also wards for infants and children. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope. Three resident pupils are selected half-yearly. Prize examinations, including examinations for the Hudson Scholarship, 30*l.*, and a gold medal, and a senior prize of 10*l.*, and a silver medal, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry.

Sir Patrick Dun's Hospital is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It was founded by the School of Physic Act in 1800, and is now governed by the directions laid down in that statute and in the School of Physic Amendment Act, 1867, and it is officered exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was a purely medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now perfectly free to all students.

Mater Misericordiæ Hospital.—This is one of the largest and best provided hospitals in Dublin, and is in great measure under the management and patronage of the Catholic Hierarchy; it contains 230 beds; 50 beds are reserved for fever and other contagious diseases. A special course of lectures on fever will be given during the session. A ward has been assigned for the treatment of ophthalmic diseases, in accordance with the requirements of licensing bodies. The Leonard prizes, value of 30*l.*, will be given at the end of the winter session. The Introductory Lecture will be delivered by Dr. Redmond on October 31st, at 11 a.m.

Mercer's Hospital, William Street, founded A.D. 1750.—This hospital, which is intimately associated with the Ledwich School though it educates students of all schools, is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are opened at all hours for the reception of accidents and of acute cases. Dispensaries are held daily and are largely attended. Special instruction is given in cutaneous, infantile, gynæcological, and ophthalmic diseases. From the large number of accidents which, from its position, come to the hospital, students are offered ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms, and of acquiring dexterity in the dressing and manual operations of minor surgery.

St. Vincent's Hospital was established as a middle catholic hospital, in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The hospital has 160 beds constantly full, and each sister has charge of about twelve patients. In connection with it is the convalescent home at Linden Grove, Blackrock. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. Cox, and Dr. J. S. McArdle. A special ward for the treatment of the diseases of women has been opened under the care of Dr. J. A. Byrne, gynæcologist to the hospital. The ophthalmic department is conducted by Mr. D. Redmond. The resident officers consist of a house-surgeon (Mr. Denis P. Kenna) and two resident pupils. The hospital is visited daily at 9 a.m., and patients are admitted at 10 a.m. Accidents and urgent cases, however, are admitted at all hours. Special arrangements have been made to afford facilities to the students for the study of infective fevers.

Dr. Steevens's Hospital, containing beds for 250 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. There is accommodation for residence of two medical and six surgical pupils, besides whom the house-surgeon receives house pupils. The fees payable for the privilege of residence are twenty guineas, winter; fifteen guineas, summer six months, which includes the fee for hospital practice for the corresponding terms, and the students in addition to their rooms and furniture are provided with coal and gas. The hospital is easily accessible by two lines of tramway, one of which terminates at the Kingsbridge station within one minute's walk of the hospital.

Jervis Street Hospital is one of the oldest-established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character supplies the hospital with an abundance of surgical cases. It is frequented by Catholic students, and its nursing arrangements are under the charge of a community of Sisters of Mercy. The hospital being found inadequate to the demands upon it, is in process of being rebuilt, and, when finished, will be one of the finest hospitals in Dublin.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda and Coombe Lying-in Hospitals, Cork Street Fever Hospital, Pitt Street Children's Infirmary, St. Mark's Ophthalmic Hospital, the National Eye and Ear Hospital, two Dental Hospitals, the Throat Hospital, and two Orthopædic Hospitals.

The Rotunda Hospital.—This well-known and time-honoured institution possesses a character as a school of midwifery which needs no comment. It is not, however, as generally recognised as it deserves to be as also a great school of gynæcology. The institution consists, in fact, of two distinct hospitals—viz., the lying-in hospital, into which some 1,200 cases of labour are admitted annually; and the hospital for the treatment of diseases peculiar to women, into which some 500 patients are now admitted during the course of the year. The present master is Dr. Macan, well known to gynæcology as Lecturer in the Carmichael College, and obstetrician to the City of Dublin Hospital. There is also a large extern maternity in connection with the hospital. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination. The clinical clerkship, value 50*l.* a year, tenable for six months, is adjudged, after open competitive examination, to any pupil who has attended the full course of instruction in the hospital.

Coombe Lying-in Hospital.—This hospital, which was rebuilt, considerably enlarged, and refurnished some years ago, contains 65 beds. It was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1867, thus enabling its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than 2,000 in number. Moreover, the chronic hospital for the reception of cases of the diseases of females gives admission to about 200 patients annually. The fee for attendance is 8*l.* 8*s.* for six months as extern, and 18*l.* 18*s.* as internal pupil. During that period the student attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships and a clinical clerkship are obtainable half-yearly by all pupils who have obtained their midwifery diplomas from the hospital, and special certificates are given. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside.

Cork Street Fever Hospital and House of Recovery is the only special fever hospital in Dublin. It contains 200 beds, and is supported mainly by an annual Government grant, supplemented by voluntary contributions. A certificate of attendance on fever being now required of candidates for the licence to practise medicine of the King and Queen's College of Physicians in Ireland, arrangements have been made whereby the exceptional advantages connected with this institution can be utilised for purposes of clinical teaching. All particulars may be obtained on application to the Registrar and Resident Medical Officer.

The Pitt Street Children's Infirmary, established 1821, was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill are the medical officers.

Dublin Orthopædic Hospital, 11 Usher's Island, containing 30 beds for the treatment of every class of deformities and the practice of orthopædic surgery. The institution is under the management of Mr. Swan.

National Orthopædic and Children's Hospital for the treatment of club-foot, contractions and distortions of the limbs, spinal and other bodily deformities, and all non-infectious diseases peculiar to children, 7 Adelaide Road, Dublin. Mr. Ormsby attends on Mondays, Wednesdays, and Fridays; Dr. Woodhouse on Tuesdays, Thursdays, and Saturdays, from 10 to 11 o'clock, and gives clinical instruction on the intern cases. The hospital is capable of containing 30 beds, for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Fridays. Students and practitioners are allowed to attend the clinical instruction.

St. Mark's Ophthalmic Hospital and Dispensary for

Diseases of the Eye and Ear.—This hospital was founded by the late Sir William Wilde, and contains 38 beds. Clinical lectures are delivered on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, at 11 o'clock, and operations are performed on Wednesdays and Saturdays at the same hour. An ophthalmic class meets at 4 p.m. on Mondays, Tuesdays, Wednesdays, and Thursdays.

National Eye and Ear Infirmary, Molesworth Street.—This hospital contains 26 beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, and a systematic course of lectures, is given daily. Operations at 12 o'clock. Instruction in aural surgery is also given. The certificate in clinical ophthalmology from this hospital is recognised by the Board of T.C.D. Students may enter their names for the three months' course any day from 1st October to 1st April.

The Dental Hospital of Ireland, 29 York Street, will re-open for the new session on Monday, October 8th, 1883. Courses of lectures in the special subjects required for the dental curriculum will be given at the hospital, viz., lectures on dental surgery, dental anatomy, mechanical dentistry, and metallurgy. Students will be admitted to these and to the practice of the hospital on the same conditions as are in force at the Dental Hospital of London. These conditions can be obtained from Mr. William Shea, the Hospital Registrar. In addition to the courses for the dental curriculum, the shorter courses for surgeons of three and six months' hospital practice will be continued.

II.—QUALIFICATION.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, medical students gravitate into one or other of three classes :—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the Licences of the College of Surgeons with that of the College of Physicians or of the Apothecaries' Hall. *c.* Those who will take their qualifications at the new Royal Irish University, because graduation in Arts is not necessary in that institution. A fourth minor class is constituted by those who pursue their studies in Ireland, but who, either to escape the extended course of study required in Ireland, or to save the consequent fees, or because they cannot pass the Irish examination, migrate to Edinburgh or Glasgow for their licences. Almost all these emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, almost without exception, in Dublin.

The Irish licensing bodies are as follows :—

The University of Dublin grants the degrees of M.B. and B.Ch. to students who have obtained their Arts degree, and the higher degrees of M.D. and M.Ch. to to those who have held for at least three years the grade of M.B. and B.Ch. It does not grant degrees to undergraduate students; consequently its licences hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degree of Bachelor in Medicine and Bachelor in Surgery in the University of Dublin is approximately as follows :—Lectures, £61 13s.; Hospitals, £44 2s.; Degree Fees, £31—£136 15s.

The expense of the degree of Bachelor in Arts, amounting altogether to £83 4s., should be added to the foregoing, making the total cost £230.

The University also grants a midwifery degree (M.A.O.) to its own medical graduates, at an additional fee of £5.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.—Candidates must be graduates in Arts, and may obtain the degree at the same commencement as the B.A., or at any subsequent one. The medical education of a Bachelor of Medicine is of four years' duration, and comprises the following lectures :—

Winter Courses.—Anatomy; physiology; practical anatomy; surgery; chemistry; practice of medicine; midwifery; heat, electricity, and magnetism.

Summer Courses:—Botany; materia medica; and pharmacy; practical histology; medical jurisprudence; comparative anatomy. Hospital attendance on a medico-chirurgical hospital during three courses of nine months each, with clinical lectures, including actual attendance on fever; six months' practical midwifery; six months' dissections; and three months' laboratory instruction in chemistry are required. The courses may be attended at any recognised medical school. The fee for the *Liceat ad Examinandum* is 5*l.* The fee for the degree of M.B. is 11*l.*

Doctor in Medicine.—A Doctor in Medicine must be M.B., or qualified to take that degree for three years. He must also read a thesis before the Regius Professor of Physic. Total fee for this degree, 13*l.*

Bachelor in Surgery must be B.A., have spent four years in the study of surgery and anatomy, and passed the M.B. examination. The curriculum comprises the following, in addition to the course for the M.B.:—Theoretical and operative surgery, one course; Dissection, two courses; Ophthalmic surgery, one course. Candidates are required to perform operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5. Fee for the degree of Bachelor in Surgery, £5.

Master in Surgery must be a B.Ch. of three years' standing, and must read a thesis. For the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations, and produce certificates of having completed the following curriculum:—1. One Winter Course in Midwifery. 2. Six months' practice in a recognised lying-in hospital or maternity. 3. A Summer Course in obstetric medicine and surgery. 4 Two months' practice in the Cow-pock Institution, or in the Grand Canal Street Dispensary. Graduates of medicine of M.D. standing may present themselves for examination without complying with Regulations 3 and 4. Fee for the degree of M.A.O., £5.

Candidates for the licence in medicine or surgery must be matriculated in medicine, and must have completed *two years in Arts.*

Licentiate in Medicine.—The course and examination are the same as for the M.B. An L.M. on proceeding to the degree of B.A., may become an M.B. on paying the fees without further examination. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in medicine, £5.

Licentiate in Surgery.—The course and examination necessary for the licence in surgery is the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5. Fee for the licence in surgery, £5.

The Royal Irish University.—This institution entered on its work as a licensing body within the past year. The degrees of the University are granted on one year's Arts, *i.e.*, the matriculation examination of the University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £69. The examinations are conducted not only in Dublin, but at certain local centres.

The University confers the following medical degrees :—

Bachelor of Medicine, M.B.; Doctor of Medicine, M.D.; Master of Surgery, M.Ch.; in Obstetrics, a special diploma; in Sanitary Science, a special diploma.

All degrees are open to persons of either sex. The examinations for women are held apart from those for men, but upon the same days.

The University examinations commence on the third Tuesday in September.

Candidates for any degree must have passed the Matriculation Examination of the University. *Students from other Universities are included.*

This examination shall be conducted not only in Dublin, but at certain local centres selected by the Senate.

Every candidate must send in to the secretaries his name and address, and pay a fee of 10s.

The following are subjects:—

I. Latin. II. Any one of the following languages:—Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic. III. English language. IV. Elementary Mathematics. V. Experimental Physics.

Candidates for all degrees must pass the First University Examination.

The courses for the degrees of M.B. and B.Ch., and the Diplomas in Obstetrics and in Sanitary Science, extend over at least four years. Candidates will be required, in addition to the First University Examination, to pass the following Examinations:—*a.* First Professional Examination. *b.* Second Professional Examination. *c.* The Degree Examination. They may, however, pass the First University Examination at the same time as the First Professional Examination.

Candidates for the M.D. may present themselves after the lapse of two Academical years from the date of obtaining the degree of M.B. Those candidates who are Students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the Degree Examination.

Students will be admitted to this Examination after one Academical year from Matriculation. Fee £1.

Candidates at this Examination will be required to answer in the following subjects:—

I. Latin. II. Any one of the following languages, viz.: Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic. III. English language and Literature. IV. Mathematics. V. Experimental Physics.

The first period of Medical Study shall comprise—*a.* Chemistry, six months; *b.* Practical Chemistry, three months in a chemical laboratory; *c.* Botany, with Herborization for practical study, and Zoology; *d.* Anatomy and Physiology; *e.* Practical Anatomy; *f.* Materia Medica. The second period—*a.* Anatomy and Physiology, including Histology; *b.* Practical Anatomy; *c.* Theory and Practice of Surgery; *d.* Midwifery and Diseases of Women, six months; *e.* Theory and Practice of Medicine; *f.* Medical Jurisprudence.

Candidates are further required to have attended during the First period—Medical-Chirurgical, a winter of six months; and during the Second period—Practical Midwifery, Midwifery Hospital, six months, or six months at a Midwifery Dispensary where similar clinical instruction is given (the certificate must state that the candidate has attended at twenty labours); Medico-Chirurgical Hospital, eighteen months, including either three winters, or two winters and two summers.

Candidates must also before the Degree Examination produce certificates — (1) of personal attendance on fever cases; (2) of having compounded under an apothecary or pharmaceutical chemist for at least three months; (3) of instruction in vaccination; (4) of having attended a course of lectures (not less than 25) and clinical instruction on Mental Diseases.

FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The fee for this Examination is £1.

The subjects—*a.* Zoology; *b.* Botany; *c.* A Modern Language.

Candidates who have passed in a Modern Language at the ordinary First University Examination are exempt from presenting this subject.

SECOND UNIVERSITY EXAMINATION IN MEDICINE.

The Second University Examination in Medicine comprises the following subjects: — Anatomy, Physiology, Materia Medica, and Chemistry. Before being admitted to this Examination, each student must produce satisfactory evidence of having completed the course recommended for study during the first period. Fee, £1.

EXAMINATION FOR THE M.B. DEGREE.

Fee, £3. Each candidate must produce certificates of having completed all the prescribed courses. The Examination comprises the subjects recommended for study during the second period, and includes Examinations in Clinical Medicine and Clinical Surgery.

EXAMINATION FOR THE M.CH. DEGREE.

Conferred only on graduates in Medicine of the University. Fee, £5. The Examination comprises Theory and Practice of Surgery, including Operative and Clinical Surgery.

EXAMINATION FOR THE DIPLOMA IN OBSTETRICS.

Conferred only on graduates in Medicine of the University. Fee, £2. The Examination comprises Theory and Practice of Midwifery, and the use of obstetrical instruments and appliances.

EXAMINATION FOR THE DIPLOMA IN SANITARY SCIENCE.

Conferred only on graduates in Medicine of the University. Fee, £2. The Examination shall embrace the following subjects:—Climate, Chemistry, Geology, Physics; Vital Statistics; Hygiene, Sanitary Law. The Examination in Chemistry shall include a practical part on the chemical and microscopical examination of air, water, food, poisonous substances used in manufacture, &c. The Examination in Physics shall embrace the reading of plans, sections, scales, &c., in connection with buildings, sanitary constructions, &c.

EXAMINATION FOR THE M.D. DEGREE.

Fee, £5. The degree of Doctor may be conferred on any candidate who has obtained the M.B., and has produced a certificate of having been for the last two years engaged in hospital or private medical or surgical practice, or in the military or naval medical service, provided that the candidate shall submit to the medical examiners a thesis composed by himself, and approved by them. No thesis will be approved which does not contain some original or personal observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

Candidates settled for a period of two years in the colonies or foreign countries may, on satisfying the Senate to that effect, and complying with the conditions above described, have the degree conferred on them in absence.

The Royal College of Surgeons' licence, or L.R.C.S.I., is universally sought for by those students who do not resort to a University. Great and important changes have been made in the system of granting these licences within the past year. Henceforth every candidate must pass four professional examinations—one at the end of each year of study—as follows:—*a.* Preliminary scientific; *b.* Preliminary professional; *c.* Theoretical; *d.* Practical. The preliminary scientific (*a*) may be studied for at home; the other examinations involve teaching in a medical school. The College holds the only extra-university preliminary examination, save that of the Apothecaries' Hall. It grants the higher qualification of Fellow, or F.R.C.S.I., to those who are specially qualified and specially examined for that diploma, and it also confers a midwifery diploma on examination by a special Court of Examiners.

As it is our business especially to provide information for the student who is about to commence his first year of study, we substitute the new scheme, compulsory upon all students who commenced their studies after July, 1882, for the old regulations (which may be found in the Irish Medical Directory); but it is to be remembered that students who have already commenced medical study may present themselves either under the old or new system.

We call the special attention of students who intend taking the L.R.C.S.I. to the fact that for the future they *must* pass their preliminary examination, and register themselves at the Branch Medical Council, 35 Dawson Street, within fifteen days of the time at which they enter on medical study, otherwise their lecture and hospital certificates for courses commenced before they have done so will not count.

The Matriculation Examination of the Royal University and the pass in the requisite subjects at the Intermediate Examination are now recognised as equivalent preliminary examinations.

THE NEW SCHEME OF THE EDUCATION AND EXAMINATION FOR THE L.R.C.S.I.

Every candidate shall produce evidence—1. Of having, before entering on medical studies, passed the preliminary examination of the College, or an equivalent examination in general education, recognised by the General Medical Council; and, 2. Of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised by the College if the date of commencement of the course to which the certificate refers is more than fifteen days prior to such registration.

This College recognises as the commencement of professional study:—1. Attendance on the practice of a hospital or other public institution recognised by the College for that purpose; or, 2. Instruction as pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council; or, 3. Attendance on lectures on anatomy, physiology, or chemistry, by lecturers recognised by this College.

The letters testimonial of the College shall not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student; or to any one who has not attained the age of twenty-one years.

Registered Pupils of the College.—Any student may be registered as a pupil in the College books on payment of a registration fee of £5 5s., for which credit will be given subsequently in his examination fee. No student can be admitted as a candidate to examination until he shall have been so enrolled, and passed the preliminary examination.

Examinations.—Every candidate must pass a preliminary examination and four professional examinations. Candidates who possess a diploma or degree in either medicine or surgery, or who have passed a sufficient examination in these subjects, may be exempted from compliance with this rule.

Candidates must return their names, fees, and certificates one week before examination.

Preliminary Examination.—All students *must* pass their preliminary examination before entering upon their professional studies.

The preliminary examinations are held quarterly—viz., on the 3rd Wednesday in Jan., April, July, and Oct., in the following subjects, with permission to the student to select French, German, or Greek:—1. English, including grammar and composition; 2. Arithmetic, including vulgar and decimal fractions; 3. Algebra, including simple equations; 4. Geometry, first two books of Euclid; 5. Latin—the first and second Books of the Æneid of Virgil, or the Jugurthine War of Sallust, or the Third Book of Livy; 6. Physics, as may be found in Ganot's Popular Natural Philosophy. The examination in physics may be passed either at the preliminary or the first professional examination.

Alternative subjects—one to be selected by the student:—1. Greek—the Gospel of St. John, or the First Book of Xenophon's Anabasis, or the Dialogue of Lucian, entitled "Menippus, or the Necromancy;" 2. French—Fénélon's "Télémaque;" 3. German—Schiller's "Wilhelm Tell."

Fees.—Registered pupils of the College free. Non-registered pupils, £1 1s. Rejected candidates, whether registered pupils or not, shall pay a further fee of £1 1s. for each re-examination.

Professional Examinations.—The 1st, 2nd, and 3rd professional examinations shall be held in the July and October of each year. Should the student fail to pass in July he may present himself at the examination held in October.

The examination of each year must be passed before a new session can be entered on.

First Professional Examination.—Candidates must, before admission to the first preliminary examination, produce evidence of having passed the preliminary examination, and of having been registered as students, and of having been engaged in study for at least nine months after registration.

Candidates are recommended to attend a course of lectures on practical anatomy, and one on chemistry, before this examination.

The examination shall include the following subjects, viz.:—1. Physic, if not passed at the preliminary examination; 2. The elements of chemistry, as may be found in Roscoe's Lessons in Elementary Chemistry, from chap. i. to xiii., inclusive; 3. Botany, as may be found in Oliver's Lessons in Botany, Part I., with descriptions of the following plants:—The buttercup, poppy, pea, strawberry, fox-glove, and dandelion; 4. Anatomy—human osteology; 5. Practical Pharmacy—Elementary.

Fees.—The fee for this examination shall be £5 5s., in addition to the registration fee of £5 5s. Neither of these fees shall be returned in case of rejection, but the candidate on paying an additional sum of £2 2s. shall be admitted to re-examination.

Second Professional Examination.—Candidates must produce evidence of having passed the First Professional Examination, also certificates of having subsequently attended: Hospital, nine months; Winter Courses: Practical anatomy, with demonstrations and dissections; physiology; surgery; chemistry (unless attended in first year); Summer Courses, three months: Practical chemistry, practical physiology, materia medica.

Fees.—The fee for this examination shall be £5 5s. Candidates who are rejected will be admitted to re-examination on paying an additional fee of £2 2s.

Candidates shall be examined in: 1. Anatomy—bones, joints, muscles, and topographical anatomy of the viscera of the chest, abdomen, and pelvis; 2. Histology, and the physiology of the circulatory, respiratory, and digestive systems; 3. Surgery—the signs, terminations and treatment of inflammation, wounds, hæmorrhage, burns and scalds, ulcers, and bandaging; 4. Chemistry; 5. Materia medica.

Third Professional Examination.—Candidates must produce evidence of having passed the second examination; also certificates of hospital; nine months as an extern pupil, or six months as a resident pupil. Winter Courses—Demonstrations and dissections, practical anatomy (unless attended in the first year), surgery, medicine. Summer Course, three months—Medical jurisprudence.

Fees.—The fee for this examination shall be £5 5s.; and for re-examination, if rejected, £2 2s.

Candidates shall be examined in: 1. Anatomy; 2. Physiology; 3. Surgery, not including operative, clinical, and ophthalmic surgery, which are reserved for the final professional examination.

Fourth, and final, Professional Examination.—The fourth examination shall be held in July and October, and in the following April. Candidates must produce evidence of having passed the third examination; also of having attended hospital nine months as extern pupils, or six months as resident pupils, unless a certificate to that effect has been accepted in the third year. Winter Courses — Dissections and demonstrations; midwifery, a midwifery hospital, or maternity, for six months, and of having been present at thirty labours. (May be attended in the third or fourth year, winter or summer.) Operative surgery. Practical instruction in vaccination. (May be attended at any time after registration.)

Fees.—The fee for this examination shall be £5 5s.; and £2 2s. for re-examination, if rejected.

Candidates shall be examined in: 1. Surgery, clinical, ophthalmic, and operative, with surgical anatomy; 2. Medicine; 3. Midwifery and diseases of women; 4. Medical jurisprudence.

The King and Queen's College of Physicians grants its licence, L.K.Q.C.P.—the usual medical qualification of the Irish student—which is almost always taken by the young surgeon immediately after his passing at the College of Surgeons, and for it the same curriculum of study is sufficient. The College has recently established a higher qualification of "Member," for which there is a special examination, and there is also the still higher grade of Fellow of the College, to which admission is by ballot, without examination or curriculum.

The cost of obtaining the L.R.C.S.I., with the L.K.Q.C.P.I., and the licence in midwifery, is nearly as possible as follows:—

Lectures, &c.	£65	0	0
Hospital	37	16	0
Diploma fees, L.R.C.S.... ...	26	5	0
Diploma fees, L.K.Q.C.P Diploma fees, Lic. Mid. ...	16	16	0
	£145	17	0

A certificate of study in vaccination and a course of

clinical instruction in ophthalmology are now required. A course of attendance at a midwifery hospital is required for the midwifery diploma. With these additions, the total expense of the Dublin double diploma may be set down at £155.

THE MEMBERSHIP OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.

I.—The grade of Members is distinct from that of the Fellows, and the members as such are not members of the Body Corporate.

II.—Members alone are eligible to the Fellowship. They have the use of the reading rooms and library.

III.—Licentiates admitted before December 12th, 1878, are entitled to be admitted Members of the College without payment or examination, on giving six weeks' notice, in writing, to the Registrar.

IV.—Every candidate for membership must produce evidence—1. Of being over 25 years of age. 2. Of being a licentiate of the College for three years at least; or, a licentiate of one year's standing, if also a graduate of arts; or, a licentiate of one year's standing, if also a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character. 4. That he is not engaged in trade; and that he does not dispense medicine, or make any engagement with a chemist or any other person for the supply of medicine; nor practise medicine or surgery in partnership, by deed, or otherwise. (Candidates for the membership by examination must, in addition to the above, show proof as follows):—5. Of having been for six months resident physician, or resident pupil, in a recognised hospital; or for same period as clinical clerk in the medical wards, or in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 6. Of having paid the fee of twenty guineas.

V.—Every candidate must pass *examination in the following subjects*:—1. Principles of Medicine, including Pathology, Medical Anatomy, and Medical Chemistry. 2. Practice of Medicine, including Principles of Public Health. 3. Clinical Medicine.

Oral Examination.—This examination includes the investigation of morbid specimens, the qualitative analysis of animal products, the detection of poisons, and the use of the microscope.

LICENCES IN MEDICINE AND MIDWIFERY.

I.—Examinations for the licences of the College in medicine and midwifery are held in the week following the first Friday in each month, except August and September.

II.—Every candidate for either licence must return his name to the registrar, and lodge his certificate, bank receipt of fees, and his schedule, at least *four* days before the first Friday in each month.

THE L.K.Q.C.P.I.

Every candidate is required to produce satisfactory evidence—

1. Of character, from a Fellow of the College, or from two registered practitioners.

2. Of having passed an examination in general education held by some of the recognised examining bodies.

3. Of having been engaged four years in the study of medicine.

4. Of having attended lectures on the following subjects at recognised schools:—

Practical Anatomy, two courses. Physiology, or Institutes of Medicine, one course. Chemistry, one course. Practical Chemistry, one course. Materia Medica, one course. Medical Jurisprudence, one course. Practice of Medicine and Pathology, one course. Surgery, one course. Midwifery, one course.

5. Of twenty-seven months' attendance at a recognised medico-chirurgical hospital, in which clinical lectures and clinical instruction in medicine are given, the attendance not to be for more than nine months in any one year, and of having for not less than three months studied fever in a recognised clinical hospital containing fever wards, and recorded, from daily personal observation, at least five cases of fever to the satisfaction of the attending clinical physician, as attested by his signature.

6. Of having attended practical midwifery and diseases of women for six months at a recognised lying-in hospital or maternity; or, where such hospital attendance cannot have been obtained during any part of the student's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding public appointments; not less than twenty labour cases to be actually attended.

III.—The professional examination is divided into two parts—

First Part—Anatomy, physiology, practical histology, chemistry, and materia medica.

Second Part—Practice of medicine, clinical medicine, pathology, medical jurisprudence, midwifery, hygiene, and therapeutics.

IV.—Any registered practitioner of *five* years' standing shall be admitted to examination for the licence of the College, on producing his certificate of registration, with satisfactory reference, and shall have the privilege of being exempted from the examination by printed questions.

THE LICENCE IN MIDWIFERY.

Candidates for the licence in midwifery who are not licentiates in medicine may be admitted to examination on the following qualifications:—

(1) The degree or licence from any University or College in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (a) a course of lectures on midwifery in a school recognised by the College; (b) practical midwifery and diseases of women, for six months, at a lying-in hospital, or maternity, recognised by the College; or, *where such hospital attendance cannot have been obtained during any period of the candidate's course of study*, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment, the certificate in each case to state that not less than twenty labour cases have been actually attended.

Candidates who are already licentiates in medicine of the College, or who have passed the examination for such licence, may be admitted to examination for the licence in midwifery on lodging their fees, and signifying their wish to the registrar a week at least before such examination.

Any registered practitioner of *five* years' standing shall be admitted to examination for the licence in midwifery on producing his certificate of registration, with satisfactory reference; and he shall have the privilege of being exempted from the examination by printed questions.

A Certificate in Sanitary Science is granted to licentiates of the College who shall pass an examination in the following subjects—viz., Ætiology and prevention of disease, sanitary law and engineering, chemistry, vital statistics, and meteorology with climatology.

Examinations for this certificate are held on the Thursday following the first Friday of January, April, July, and October, and at such other times as the President shall appoint.

Every candidate for the certificate must be a licentiate of the College, and must return his name to the registrar a week before examination, and lodge a testimonial of character from a Fellow or Member of a recognised College.

FEES FOR LICENCES AND EXAMINATIONS.

Licence in medicine, 15 guineas, which may be divided as follows: For examination at the termination of the first period of study, 5 guineas. For final examination for the licence, 10 guineas.

N.B.—The fee for the licence to graduates in Medicine and Arts of any University in the United Kingdom—*five* guineas.

Licence in midwifery, 3 guineas.

Fee for examination for the licences in medicine and midwifery, if obtained within the interval of a month, 16 guineas—to be lodged in one sum.

Fee for special examination for the licence in medicine, 20 guineas.

Fee for special examination for the licence in midwifery, 5 guineas.

Fee for the certificate in sanitary science, 5 guineas.

The Apothecaries' Company grants a registrable licence (L.A.H.), which is accepted by the Local Government Board and by the Army and Naval Boards as a medical qualification, and which, in addition, entitles the holder to keep open shop and sell drugs in Ireland. It only costs 10s., and it is taken in lieu of the licence of the College of Physicians by a few students to whom the money cost of their qualification is vitally important, or who intend to open an establishment in some of the provincial towns for the dispensing of medicines. The cost of the L.A.H., with the necessary curriculum of study, is about £59; that of the L.R.C.S.I., combined with the L.A.H. and a licence in midwifery, is about £130.

THE ARTS EXAMINATIONS

Will be at the Hall four times in the year—viz., the third Thursday in the months of January, April, July, and October, at the hour of 12 o'clock noon.

The examination for the *Licence* is divided into two parts:—

The first part comprehends chemistry, botany, anatomy, physiology, materia medica, and pharmacy.

The second—medicine, surgery, pathology, therapeutics, midwifery, forensic medicine, and hygiene.

THE PROFESSIONAL EXAMINATIONS

Will be held quarterly, on the first and second Monday in January, April, July, and October.

Subjects—First Part: Chemistry, botany, materia medica and pharmacy, anatomy and physiology.

Second Part: Medicine, surgery, midwifery and diseases of women and children, forensic medicine, hygiene, and clinical examination.

The first three hours of each day will be devoted to writing answers, and afterwards there will be two hours to an oral and practical examination.

Candidates at the examination on anatomy are liable to be called on to perform dissections; and at the examination on surgery, to perform one or more operations on the dead subject.

Doctors of medicine and licentiates of a College of Physicians who have also spent twelve months at practical pharmacy may obtain the licence by undergoing an examination—the former in surgery and pharmacy, and the latter in medicine and pharmacy. Licentiates of the London Society of Apothecaries must undergo an examination in surgery.

Queen's University in Ireland.—This University has ceased to exist, being superseded by the Royal Irish University, which held its first matriculation examination last year. All medical graduates are, *ipso facto*, entitled to become medical graduates of the Royal Irish University. The existing students in medicine of the Queen's University will also, on obtaining their degree from the Royal Irish University, be entitled to receive the title of M.D., which, under other circumstances, will be granted only to full graduates in Arts.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The above Society was instituted by the Pharmacy Act (Ireland) in 1875, 38 & 39 Vict., cap. 57. In that Act it is stated that whereas a great deficiency existed throughout Ireland of establishments for the sale of medicines and compounding of prescriptions, and that great inconvenience therefore arises to the public, it is expedient to amend the Act of 1791 (the Apothecaries' Act). A president (Sir Dominic Corrigan) and vice-president (Dr. Aquilla Smith), with a council of twenty-one men, were named by the Government to carry out the provisions of the Act. In 1878 Sir Dominic Corrigan resigned the presidentship. The present president is Professor Tichborne, and the vice-president Dr. Aquilla Smith. The pharmaceutical chemist is not allowed to prescribe. In this respect he differs from the apothecary. All persons who keep open shops for compounding prescriptions must hold the licence of the Pharmaceutical Society or the Apothecaries' Hall. Pharmaceutical chemists under the Act are entitled to hold the office of apothecary to district lunatic asylums, county gaols, and by a recent order of the Local Government Board, may also hold workhouses and dispensaries. The Society, according to their Calendar, which was corrected to the 31st December, 1882, had 219 licentiates. They hold evening meetings during the winter for the reading and discussion of pharmaceutical papers and scientific papers bearing on pharmacy. This Society has power under their Act to prosecute persons illegally compounding.

◆

THE IRISH QUEEN'S COLLEGES.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any such relation to a central examining body, but educate students for all colleges and degrees. But they will be maintained, as hitherto, by a handsome Government grant, and the same curriculum as that heretofore adopted will be continued. The various exhibitions and scholarships will still be available. Each College has the disposal of about £450 per annum in scholarships. The curriculum is generally well adapted for preparation for the new University examinations. The Colleges are well adapted for high-class technical education, having lecture-rooms provided with every appliance necessary in the modern training of a medical student. The great want in the Colleges of Cork and Galway is a summer session. This necessitates the loss to the student each year of three available working months, and deprives him of his practical hospital work in the summer session, both general and special. The courses of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in two-thirds of a course. The winter session commences on November 1st, and ends May 31st. The scholarship examinations are held in October. A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information, will be found in the advertisements of this issue, and full details may be had on application to—

Belfast—John Purser, M.A., Registrar.
Cork.—Alexander Jack, M.A.
Galway.—Edward Townsend, M.A.

◆

TECHNICAL EDUCATION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE, STEPHEN'S GREEN, DUBLIN.

This College supplies a complete course of instruction in science, applicable to the industrial arts, especially those which may be classed broadly under the heads of Chemical Manufactures, Mining, and Engineering. A diploma of Associate of the College is granted at the end of the three years' course. There are four Royal scholarships of the value of £50 each yearly, with free education, including laboratory instruction, tenable for two years. Two become vacant each year. They are given to students who have been a year in the College. The chemical and physical laboratories and drawing school are open daily for practical instruction. The session commences on Monday, October 1st.

THE IRISH DIPLOMA IN DENTAL SURGERY.

The examiners for the L.D.S.R.C.S.I. consist of three Fellows of the College, three registered dentists, and the President, Vice-President, or other member of the Council of the College (summoned in rotation).

The examinations embrace the anatomy, physiology, surgery, and pathology of the teeth, jaws, and surrounding parts, and mechanical dentistry, and shall be partly written and partly oral.

All candidates shall lodge at least one fortnight previous to each examination—

I. A certificate of having attained the age of 21 years.
II. Receipt for the fee of 10 guineas.

Every successful candidate, previous to receiving the licence, shall declare that he will not advertise, or pursue any other unbecoming mode of attracting business, so long as he holds the licence in dentistry of the College.

The dental hospitals of Ireland are—that in York Street, Dublin, respecting which information will be found under the heading "Special Hospitals," and the Dublin Dental Infirmary, in Beresford Place.

Note.—Our advertising columns, of which an index will be found at the end of the editorial matter, will supply further information, with the names of the staff, &c., attached to the foregoing schools.

INTRODUCTORY LECTURES IN THE DUBLIN SCHOOLS AND HOSPITALS.

Royal College of Surgeons—None.
University School of Physics—No information.
Catholic University School—None.
Ledwich School—None.
Carmichael College—None.
Richmond Hospital—None.
Meath Hospital—No information.
City of Dublin Hospital—None.
Adelaide Hospital—No information.
Mercer's Hospital—None.
Mater Misericordiæ Hospital—Dr. Redmond; October 31, at 11 a.m.
St. Vincent's Hospital—Dr. McArdle; October 26, at 11 a.m.
Jervis Street Hospital—None.
Steevens's Hospital—None.
Rotunda Hospital—None.
Coombe Hospital—No information.
St. Mark's Hospital—None.
Sir P. Dun's Hospital—None.

Scotland.

Medical education in Scotland has recently been subjected to searching criticism in connection with the medical reform movement, which unfortunately came, at the end of the session, to so inglorious a termination. The feeling was widespread that much of this criticism was unjust, and that compared with medical education in other parts of the Kingdom, that of Scotland was in no sense inferior. Thanks to the dilatoriness, and the short-sighted and singularly unjust partiality of the Government for the system of monopoly in teaching possessed by the Universities of Scotland, the disadvantages under which extra-mural teachers labour continue for yet another year. These removed, as they must inevitably be in obedience to enlightened progress, a healthy stimulus will be given to the cause of education in Scotland, and it may safely be predicted that in the no distant future, a country which has done so much towards science will still further lay that of Medicine under greater obligations to it. All that is wanted is a fair field and no favour, the disfranchisement of corrupt monopoly in what of all things should be most free, the teaching of science; and then the best teachers will attract the most and the best students, science will be cultivated for the sake of imparting knowledge, not *farmed* as it is at present in the Universities of Scotland, error will cease to be indefinitely perpetuated by Government nominees, a better educated class of medical practitioners will emerge, the public will be better served, and much quackery, inevitably associated with meagre education, will vanish. Notwithstanding much that is indefensible on moral or political grounds in connection with medical education in Scotland, students are attracted thereto by considerations of the most weighty nature. Living, for example, is much cheaper than in the south, the cost of classes and hospital attendance is correspondingly less, there is a large field for the exercise of choice as between the various schools, the hospitals are large (possibly from the financial aspect of the question as affecting the just rights of the profession, too large), and existing in crowded centres of trade, surgical cases especially fall to be treated in great numbers.

While it is immaterial whither an industrious and well-educated student resorts for his medical education, it is undoubtedly a fact that students differentiate themselves into well-marked groups in Scotland, the well-earned *prestige* of Edinburgh attracting the largest number, and likewise the largest proportion of colonial students. Not a little of this reputation is due to the efficiency of the extra-mural teaching in Edinburgh, and any measure which would hamper this branch of the Edinburgh Medical School would exert a pernicious influence on the future educational reputation of the city. The cost of living is higher in Edinburgh than in Aberdeen and Glasgow, and hence it is the more wealthy students who resort thither. It is also stated that the preliminary education of the Edinburgh student is better than that of the other Scotch students.

During recent years much active competition has originated in Glasgow in medical teaching. The New Western Medical School and its staff have made fair claim to the consideration of the medical student; and if the teaching be good, aggressiveness is not less characteristic of the young school. Anderson's College maintains its own in the keen struggle. It has recently sustained a loss in the tranference of Dr. Barlow to the Royal Infirmary Medical School; and hence the somewhat unusual incident of a "Professor" becoming a mere "Lecturer." It is feared that Anderson's College will have considerable difficulty in securing the services of an efficient Professor of Physiology, nothwithstanding that the dignity of the title is a thing to conjure with in a rich commercial city, and among a community not generally distinguished by cultured discrimination. The backbone of Anderson's College teaching is the excellence of the instruction in the groundwork of medicine, viz., anatomy and chemistry. Under any circumstances, while these subjects continue to be taught as they are at this school, students will show their good sense in taking advantage of these classes, for without an accurate knowledge of anatomy and chemistry, many of the subsequent classes being mere appendages, it is impossible for one to be an accomplished or a thoroughly educated physician or surgeon.

The Royal Infirmary Medical School continues to make fair progress, and to attract a considerable number of students, a large proportion of whom hail from south of the Tweed. During the past year Dr. Fleming resigned the lectureship on Physiology, Dr. Barlow being appointed in his stead. There are no other changes in the staff of lecturers. The class-rooms at this school are comfortable, the reading-rooms are admirable, and altogether the equipment of the school is such that very tempting advantages are presented to the student. There is no dearth of "subjects" in Glasgow, a disadvantage under which Edinburgh labours in a marked degree.

The Aberdeen School is *par excellence* the home of the Northern Scotch student. Its staff of professors are distinguished in their respective departments, a fact sufficiently attested by the distinguished graduates which this University sends, not only to the metropolis, but to our distant and important colonies. Dr. Ogston, during the past year, resigned the chair of Medical Jurisprudence after a long and distinguished incumbency, and Dr. Mathew Hay, of Edinburgh, was recently appointed in his stead. Without the slightest disparagement to Dr. Hay, who, we believe, will prove an efficient and acceptable teacher, we cannot help thinking that in this appointment the claims of Aberdeen University itself have been ungenerously and unjustly overlooked.

In Scotland the teaching bodies are, with one or two exceptions, so inseparably associated with qualifying corporations that it is most advisable to consider them in both relations at once.

THE UNIVERSITIES.

The fees for the degrees in all four of the Scotch Universities are the same—viz., £15 15s. (£5 5s. being payable at each of the three examinations), C.M. £5 5s. (in addition to the fees of M.B.), M.D. £5 5s. (in addition to the fees for M.B.), and £10 for Government stamp.

UNIVERSITY OF EDINBURGH.

This is a qualifying and teaching body, and has complete Faculties of Arts, Theology, and Law, equally with Medicine. Prior to commencing medical studies the student must pass a preliminary examination.

Subjects of Examination from October, 1883, *to March*, 1885, *both inclusive.*—1. English: The examination will include—(1.) Writing a passage of English from dictation; (2.) English composition with the correction of sentences of bad English; (3.) Questions in English grammar, with analyses of sentences and the derivation and definition of some common English words; (4.) Questions in geography and history, especially the history of the British Islands and of English literature. 2. Latin: For Oct., 1883, and March, 1884, Livy, book xxi.; for October, 1884, and March, 1885, Livy, book x. An easy passage from a Latin prose author and a single passage of English (translated from a Latin author) to be re-translated into Latin, the more difficult Latin words being given. 3. Arithmetic: The common rules, including vulgar and decimal fractions. 4. Elements of Mathematics: Geometry, Euclid, books i., ii., and iii., or Wilson's "Elementary Geometry," books i., ii., iii. The elementary rules of algebra, including simple equations. A knowledge of geometry alone or of algebra alone will not be sufficient. 5. Elements of Dynamics (Mechanics: Elementary kinematics, statics, kinetics, and hydrostatics. Text Book: Blaikie's "Elements of Dynamics."

An examination in at least two of the following subjects is demanded before being admitted to a professional examination, in addition to the foregoing subjects—viz., 1. Greek: For October, 1883, and March, 1884, Plato, "Apologia Socratis." For October, 1884, and March, 1885, Xenophon, "Memorabilia," book i. 2. French: For October, 1883, and March, 1884, Souvestre, "Un Philosophe sous les toits," i.—ix. For October, 1884, and March, 1885, Mme. De Witt, "Derrière les Haies," chaps. i.—xvi. 3. German: For October, 1883, and March, 1884, Chamisso, "Peter Schlemichl's wundersame Geschichte." For October, 1884, and March, 1885, Schiller, "Der Neffe als Onkel." 4. Higher Mathematics: Geometry, Euclid, books i.—iv., book vi., and the propositions of book xi., usually given in the modern editions, or Wilson's "Elementary Geometry," books i., ii., iii., v., and Wilson's "Solid Geometry and Conic Sections," book iv., section 1—Algebra, Elementary Trigonometry, and Conic Sections. Text book for conic sections, Wilson's "Solid Geometry and Conic Sections," book v. 5. Natural Philosophy: Text book recommended—Balfour Stewart's "Elementary Physics." 6. Logic: Either Jevons's "Elementary Lessons in Logic," or Professor Fraser's "Selections from Berkeley," 2nd ed., pp. 143—249. 7. Moral Philosophy: For October, 1883, and March, 1884, Butler's "Ethical Theory," Sermons 1, 2, 3, and Professor Calderwood's "Handbook," pp. 1—43, 123—152, 167—202. For October, 1884, and March, 1885, (1.) Mackintosh's "Dissertations,"—Hobbes, Cudworth, Clarke, Shaftesbury, Butler, Hutchison, Hume, Smith, Price, Paley, Bentham, Stewart. (2.) Professor Calderwood's "Handbook," pp. 1—43, 77—97.

The University confers three degrees, medical and surgical qualifications being granted—M.B., M.D., and C.M. The C.M. is not conferred unless the M.B. be taken at the same time. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary education recognised by the Medical Council, A degree in Arts of any British University is held to supersede the preliminary examinations. Of the four years of professional study, one must be passed in the University of Edinburgh, and another of such four years must be in some other university entitled to grant the degree of M.D. The M.D. degree is conferred on Bachelors of Medicine who have attained the age of twenty-four years, and who present a thesis to be approved by the Medical Faculty. The lectures of several extra-mural lecturers in Edinburgh, as well as those at the London medical schools, and such teachers in the provincial schools approved by the University Court, are recognised, subject to certain conditions. The total fees for graduation, including lectures, &c., are £108 18s. For regulations as to scholarships see "Edinburgh Medical School Guide."

In Public Health.—The University confers two degrees, a Bachelor and a Doctor of Science in Public Health.

UNIVERSITY OF ST. ANDREW'S.

This University confers the degree of M.D. (certain exemptions being made to ten practitioners yearly), M.B., and C.M. Two years of study of each candidate must be in one or more of the following Universities—viz., the University of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin;

Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway. The degree of M.D. is conferred on any registered practitioner above the age of forty whose professional position is such as to entitle him to that degree, and who shall, on examination, satisfy the examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section to a greater number than ten in any one year. The examinations are held yearly towards the end of April.

UNIVERSITY OF GLASGOW.

This is both a teaching and examining body. It confers three degrees, viz., Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. Before graduating the student must have been engaged in medical study for four years, one of which must have been spent at the University of Glasgow, and the others at some university or school recognised by the Glasgow University. A *medicus annus* is constituted by two courses of 100 lectures each, or by one course of 100 lectures and two of 50 each. Two preliminary examinations must be passed, one before commencing study, and the other before appearing at the first professional examination. A degree in Arts (not honorary) exempts the student from these examinations.

Public Health.—A special examination is held in subjects relating to Public Health, and a certificate granted by the University.

Bursaries tenable by Medical Students.—The Brisbane Bursary of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed their second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly for three years, open to students of divinity, law, and medicine who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the preliminary examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum, tenable by a medical student for three years.

Both at the University of Glasgow and the University of Edinburgh numerous "extra-classes" are taught, which are *virtually* as compulsory as the regular classes of the curriculum. The expense of education is thus much greater than at first sight appears, and the student, to whom money is an object, would do well to take this matter into consideration.

UNIVERSITY OF ABERDEEN.

This University is entitled to confer degrees in all the Faculties, and is a teaching body as well. The curriculum of study is nearly the same as in the University of Edinburgh. One year must be passed at Aberdeen. Another of such four years must be either in this University or in some other University entitled to give the degree of M.D. With regard to fees each candidate for the degree of M.B. must pay a fee of £5 5s. in respect of each of the professional examinations. If he desires to be admitted to the degree of M.B. only he will not be required to pay any further fee in addition to the £15 15s.; but on admission to the degree of C.M. he must pay a further fee of £5 5s. in addition to the fees for the M.B. degree. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions. Perpetual fee for hospital practice is only £6. The professional examinations are held twice in each year, namely, in April and July, directly after the close of the winter and summer sessions.

Substantial encouragement to medical students is offered at this University in the form of bursaries.

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.D. for two years in attendance in an hospital, or in military or naval medical service, or in medical or surgical practice. Provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts, or unless he shall before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek and in Logic or Moral Philosophy.

THE COLLEGES.

Royal College of Physicians, Edinburgh.—This, like the sister College of London, is exclusively a qualifying body. In conjunction with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, this College grants a double qualification, and registrable as such. Each applicant for the professional examination must previously have passed the Arts examination of the College or one of the preliminary examinations recognised by the General Medical Council. The Preliminary examination in General Education for the diploma of each College during the year 1884 will embrace the following subjects:—

Part I.—1. English Language, including Grammar and Composition; English History; Modern Geography. 2. Arithmetic, including Vulgar and Decimal Fractions. 3. Algebra, up to and including Simple Equations. 4. Geometry; First two Books of Euclid, or the Subjects thereof. 5. Latin, including Translation and Grammar. 6. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. *Note.*—The last subject may be passed at any period previous to the first Professional Examination.

Part II.—Optional Subjects, of which one only is required to be passed:—1. Greek. 2. French. 3. German. II. The examination in English History will embrace the period from 1603 to 1714 inclusive; and in modern geography, the geography of Great Britain and its dependencies, and the principal physical features and political divisions of Europe and Asia. In Latin, the books prescribed are Ovid, Fasti, Book I.; and Cicero, De Finibus Bonorum et Malorum, Book I. and II. Besides translations from either of these, at the choice of the candidate, the examination will include grammar, translation of a passage from an unprescribed author, and translation of a passage from English into Latin, the more difficult words being supplied. In Greek, the books prescribed are Demosthenes, De Corona, first half; Sophocles, Philoctetes. Besides translations from either of these, at the choice of the candidate, parsing, derivation of English words from Greek, and translation of a passage from English into Greek are required. In French, the book prescribed is Souvestre, Un Philosophe sous les toits. Parsing and translation from English into French are also required. In German, the book prescribed is Lessing's Monna von Barnhölm. Parsing and translation from English into German are also required. III. The examinations will be held in the Hall of the College of Physicians, 9 Queen Street, on the following days, beginning each day at 1 p.m.: Tuesday, April the 8th, Wednesday, April 9th, and Thursday, April 10th; Friday, July the 4th, Saturday, July 5th, and Monday, July 7th; and on Saturday, October 11th, Monday, October 13th, and Tuesday, October 14th. The subject of the first day's examination will consist of English, History, Geography, and Latin; of the second day's examination, Arithmetic and Algebra; and of the third day's examination, of Geometry and Elements of Mechanics, and the optional subjects. Each candidate shall pay a fee of 10s. previous to the examination; and in the event of his being unsuccessful he shall pay a fee of 10s. for each subsequent examination at which he is present. Candidates are required to give their names and pay their fees to John Broome, Officer, Royal College of Physicians, Edinburgh, not less than two days prior to the day of the examination. Candidates at a distance should send their fees by post-office order. Exemption is made in the case of masters or bachelors of Arts of any British University, and certain recognised foreign Universities. Candidates who may have already passed the first professional examination of any body approved of by the College will, on completion of their studies, be admitted to the second part of the examination.

The Fellowship is conferred only by election, and the candidate must have been a member of the College for at least one year previously, and have attained the age of twenty-five years.

The Membership is conferred only on licentiates of the College or graduates of a British or Irish University after an examination in Medicine and Therapeutics, and in another branch of Medical Science to be selected by the candidate. Under certain conditions as to age and professional standing, candidates may, however, be admitted without examination.

The Licence.—The regulations are nearly the same as those for the joint examination for the Scotch double qualification.

The professional examination will be divided into two parts, according to the following arrangement of subjects:—1. Anatomy, physiology, chemistry; 2. Materia medica and pharmacy, pathology and pathological anatomy, practice of medicine, surgery, midwifery, medical jurisprudence, clinical medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing. Qualified practitioners may obtain the licence by passing an oral examination in the subjects of the second examination.

Qualification in Public Health.—The College now confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

Fees.—The fee payable by a licentiate is £15 15s. In the case of unsuccessful candidates the fee is returned, minus the expenses of examination. The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of member, he pays £21, or £15 15s., according to the date of his licence. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp-duty, which amounts to £25. All candidates for the fellowship or the membership must lodge their fees and the amount of stamp-duty payable at the time to Government with the treasurer, previously to presenting their petitions.

Royal College of Surgeons of Edinburgh.—Candidates for the diploma of this College must have followed a course of study in some University, or in an established school of medicine, or in a recognised provincial school.

Preliminary Examination.—All candidates for the diploma of the College must have passed the complete preliminary examination prescribed by the General Medical Council, and have their names inscribed on the register of medical students at the commencement of their medical studies. The preliminary examination of certain recognised bodies is accepted by the College.

Professional Study.—Candidates must have been engaged during four years after the preliminary examination in general education in professional study, which shall include not less than four winter sessions, or three winter and two summers' attendance at a recognised medical school.

Professional Examination.—The professional examination is divided into two—the one oral, the other written. The first examination embraces anatomy, physiology, and chemistry, and for this candidates may appear at the end of their second winter. The second examination embraces surgery and surgical anatomy; also medicine, midwifery, materia medica, and medical jurisprudence; and does not take place prior to the termination of the winter session of the last year of study.

The Fellowship is conferred only on candidates who have obtained a diploma from this College or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are twenty-five years of age. The election is by ballot, and three-fourths of the votes are required to be in the candidate's favour; he has also to subscribe certain bye-laws of the College. Fellows are forbidden to keep open shops, to be connected with secret remedies, or indelicate advertisements or publications. Fee is 25*l.*

The Licence.—The regulations are almost the same as those for the joint examinations conducted by the Colleges of Physicians and Surgeons. Fee is 15*l.* 15s.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a university or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. This diploma may, in certain cases, be given after examination, but *sine curriculo.* The fee is 10*l.* 10s.

THE SCOTCH DOUBLE QUALIFICATION.

The Royal College of Physicians of Edinburgh, by a certain arrangement, grants conjointly with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons, Glasgow, after one series of examinations, a double qualification, two diplomas being given and registered under the Medical Act as medical and surgical qualifications, thus: Lic. Roy. Coll. of Phys. Edin. and Lic. Roy. Coll. of Surg. Edin., or Lic. Roy. Coll. of Phys. Edin. and Lic. Fac. Phys. and Surg. Glas., according as the case may be.

By the understanding subsisting between these bodies, the College of Physicians takes exclusive charge of the examination in medicine; and the College of Surgeons or the Glasgow Faculty, of that in surgery; whilst departments common to both medicine and surgery are examined by a board in which each body is represented. Such arrangements as these were contemplated by the Medical Act, and authorised by section XIX., and those under consideration were sanctioned by the Medical Council, 7th August, 1859.

Candidates having fulfilled the full curriculum are subjected to two professional examinations. Hereafter the preliminary examination must be passed before commencing professional study, and must be otherwise conformable to the regulations of the Medical Council.

The following will be the periods of examination for the double qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh, for the year 1883-84:—

I. Preliminary Examinations in General Education.—On Saturday, Monday, and Tuesday, October 13, 15, and 16, 1883. On Tuesday, Wednesday, and Thursday, April 8, 9, and 10, 1884. On Friday, Saturday, and Monday, July 4, 5, and 7, 1884. On Saturday, Monday, and Tuesday, October 11, 13, and 14, 1884.

II. First Professional Examinations.—On Tuesday, October 9, 1883; on Tuesday, January 29, 1884; on Tuesday, April 22, 1884; on Tuesday, July 22, 1884.

III. Second Professional Examinations.—These will take place immediately after the conclusion of the first professional examinations at each of the above-mentioned periods. In no case will they be begun on an earlier day than the Thursday of any period, nor will they usually be later than that day.

Total fee for double qualification is 21*l.*

Faculty of Physicians and Surgeons, Glasgow.—The Faculty grants a licence in surgery and a fellowship. In conjunction with the Edinburgh College of Physicians it grants a double qualification. The regulations and fees are the same as the Edinburgh colleges.

School of Medicine, Edinburgh.

This, constituted by the whole body of lecturers licensed by the Colleges, meets for the purposes of teaching in separate buildings, of which Surgeons' Hall, and Minto House are the chief. At Surgeons' Hall, the parent meeting-place of the School, some of the older teachers still lecture; but owing to the want of better accommodation and the lack of that enthusiasm which characterises its younger rivals, the classes, with one or two exceptions, are not as large as they formerly were.

The lectures of this School qualify for the University of Edinburgh and the other Universities, and the Royal Colleges of Physicians and Surgeons, Edinburgh, London, and Dublin, and the other medical and surgical boards.

Total fees for double qualification, 95*l.*

For further details, see "Edinburgh School Guide."

Surgeons' Hall.—The chemical laboratories are under the care of Dr. Macadam. Medical jurisprudence laboratories—Dr. Littlejohn. Materia medica laboratories—Dr. Moinet. Dissecting-rooms—Dr. Cathcart. Pathological laboratories—Dr. Buist. Physiological laboratories—Dr. James.

Minto House.—This School is a part of the Edinburgh Extra Academical School of Medicine, and in it the following means are afforded for practical instruction :—

The dissecting-rooms are open daily from 9 a.m. till 4 p.m., under the superintendence of Mr. Symington and assistants.

The chemical laboratories are open daily from 9 a.m. till 5 p.m. for instruction in practical and analytical chemistry, under the superintendence of Mr. J. Falconer King, Mr. Hunter, and assistants.

The medical jurisprudence and public health laboratories are open daily under the superintendence of Dr. Aubrey Husband.

The materia medica museum and laboratory are open daily, under the superintendence of Dr. Craig.

Clinical instruction in diseases of women and in the minor gynecological operations is conducted in the Western Dispensary and Obstetrical Museum, under the superintendence of Dr. Halliday Croom.

The botanical laboratory is under the direction of Mr. McAlpine, B.Sc. Lond.

The physiological laboratory is open daily from 10 a.m. till 4 p.m., under the superintendence of Mr. James Hunter.

Clinical instruction in diseases of children, at the Royal Hospital for Sick Children, on Tuesdays, Thursdays, and Saturdays, at 11.30 a.m.

Clinical instruction in diseases of the ear at the Ear Dispensary, on Mondays and Thursdays at *Twelve* noon.

Clinical instruction in diseases of the skin, Royal Dispensary, on Wednesdays and Saturdays, at 1 p.m.

Clinical instruction in diseases of the throat, at the Western Dispensary, on Wednesdays and Saturdays, at 5 p.m.

The dissecting rooms and chemical laboratories open on October 1st.

Address the secretary, Mr. Falconer King.

Edinburgh Royal Infirmary. — Clinical instruction is afforded at this institution under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye and ear. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. The perpetual fee, in one payment, is 12*l.* ; the annual fee, 6*l.* 6s. ; half-yearly, 4*l.* 4s. ; quarterly, 2*l.* 2s. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

Dispensaries in Edinburgh.—At these institutions students may take out the necessary practice required by the examining bodies.

Dental School [and Hospital, Edinburgh.—The hospital practice and lectures qualify for the dental diplomas of the Royal College of Surgeons, England, Royal College of Surgeons, Edinburgh, and Royal College of Surgeons, Ireland. For further information apply to James Robertson, 4, Lindsay Place, Edinburgh, or to Mr. W. B. Macleod, Dean of the School.

Aberdeen Royal Infirmary.—Contains about 250 beds. Consulting physician : Dr. A. Harvey. Physicians : Drs. J. W. F. Smith Shand, R. Beveridge, Angus Fraser. Physicians' Assistant, Dr. D. R. Mackinnon. Surgeons : Messrs. A. Ogston, J. O. Will, R. J. Garden, and John Hall. Surgeons' Assistant : Dr. James Taylor. Ophthalmic Surgeon : Dr. Alexander D. Davidson. Pathologist : Dr. James Rodger. Chloroformist : Dr. P. Blaikie Smith. Dental Surgeon : Dr. Williamson. Pathologist and Curator of the Museum : Dr. J. Rodger. Treasurer and Secretary : Mr. W. Carnie.

Glasgow, Anderson's College.—This is exclusively a teaching body. In addition to its offering excellent opportunities for acquiring a good medical education, instruction is given in the other branches of a liberal education, advantage of which might profitably be taken by medical students generally. The expenses of this institution are exceedingly moderate, the fees for all lectures and hospital practice required of all candidates for the double qualification of the Scotch Colleges being 48*l.* Extensive opportunities for dissection are offered, under the guidance of the Professor of Anatomy.

In connection with the college there are five hospitals and dispensaries for special diseases, to all of which students are admitted.

The Summer Session at this college begins on the first Tuesday of May and closes about the middle of July. A lectureship on aural surgery has been established. Lectures on dental anatomy and surgery are also given four times weekly. The fee for two years' hospital practice required by the curriculum for the dental license is 10*l.* 10s. Fees for dental lectures are 2*l.* 2s. each course.

Appointments.—There are five physicians' and five surgeons' assistants. The appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are elected from the students.

Fees for hospital practice and clinical lectures, first year, 10*l.* 10s. ; second year, 10*l.* 10s. ; afterwards free. For six months, 6*l.* 6s. ; three months 4*l.* 4s. Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for 2*l.* 2s., or one year for 3*l.* 3s. Vaccination certificate, recognised by Privy Council, 1*l.* 1s.

Glasgow Royal Infirmary School of Medicine.—The winter session will commence on October 29th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on practical physiology, operative surgery, aural surgery, dental surgery, and diseases of the eye. During the summer lectures on insanity are given by Dr. A. Robertson, and the city parochial asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Class Fees.—For each course, first session, 2*l.* 2s. ; second session and perpetual, 1*l.* 1s. Students who have attended a first course elsewhere can enter on the second course on payment of 1*l.* 1s. Anatomy, first winter session, 4*l.* 4s. ; summer session, 1*l.* 11s. 6d ; second winter session, 4*l.* 4s. Afterwards the fee for lectures and practical anatomy is 1*l.* 1s. per session. Lectures on diseases of the ear, 1*l.* 1s. ; with clinique to those who are not students at the hospital, 2*l.* 2s. Clinique on dental surgery, free to students of the hospital ; to others, 5*l.* one year ; perpetual, 10*l.* Lectures on diseases of the eye, 1*l.* 1s. Lectures on dental surgery, 2*l.* 2s.

Glasgow Western Infirmary.—This large and well appointed infirmary is practically under the ægis of the University of Glasgow. It contains upwards of 400 beds, and there are special wards for diseases of women and diseases of the skin. Students are enrolled for attendance in the clinical classes of any of the physicians or surgeons, instruction being given by clinical lectures and demonstrations on specified days in each clinique. The hour of visit is 9 a.m. The pathological department is under the charge of Dr. Joseph Coats, and Dr. Lindsay Steven is attached to this department as pathological chemist. There is a thoroughly equipped out-patient department, diseases of the throat, aural diseases, and diseases of women and children being attended to. There are eight resident assistants in the infirmary, one being attached to the wards of each of the physicians and surgeons. They are appointed at the beginning of each session from those who have completed their course. Fees : 20 guineas for a life ticket, admitting to the infirmary and to the clinical instruction ; or the fee may be paid in two equal instalments during the first and second years. Fee for six months, 7 guineas ; and for three months, 4 guineas.

Glasgow Western Medical School, University Avenue, Hill-

head.—The winter session of this school will open on November 1st. The school is situated close to the University and the Western Infirmary, where students can obtain their clinical lectures and hospital practice. The class-rooms have been newly arranged and enlarged. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

Class Fees.—For each course of lectures, first session, 2*l.* 2s. ; second session, 1*l.* 1s. Students who have attended a first course elsewhere pay 1*l.* 1s. Anatomy, including practical anatomy, 4*l.* 4s. Summer session, 1*l.* 11. 6d.

◆

THE SERVICES.

I.—THE ARMY MEDICAL DEPARTMENT.

The Royal Warrant, dated 25th June, 1881, placed this branch of the public service pecuniarily in a better position than it had previously enjoyed. The rates of pay under that Warrant are as follows, viz.: Surgeon-General, £2 15s. a day, or if at head-quarters, £1,300 yearly ; Deputy Surgeon-General, £2, at headquarters, £900 yearly ; Brigade Surgeon, £1 10s. to £1 12s., at headquarters, £750 yearly ; Surgeon-Major, £1 to £1 7s. 6d., according to length of service, at headquarters, £650 ; Surgeon, £200 ; after five years' service, £250 a year ; after ten years' service, 15s. daily, equal to, say, £273 per annum. While on probation the surgeon receives 8s. per day. Relative rank is as follows :—As Major-General, Director-General, and Surgeon-General ; as Colonel, Deputy Surgeon-General ; as Lieut.-Colonel, Brigade Surgeon, and Surgeon-Major after twenty years' service ; as Major, Surgeon-Major of less than twenty years' service ; as Captain, Surgeon ; as Lieutenant, Surgeon on probation. The pay of medical officers is issued monthly in arrear.

A candidate must possess two diplomas or licences, one in Surgery and one in Medicine ; he must be registered. His age on appointment not to exceed 28 years. Not less than half the number of appointments to be through public competition. The Secretary of State for War may fill up the remaining number by candidates proposed by the governing bodies of schools of medicine in the United Kingdom or Colonies. Application to be made to Director-General. On passing satisfactorily through the Army Medical School at Netley he obtains his commission, the order of precedence being in that of merit at the final examination. Medical officers, soon after being gazetted to the service, are sent to Aldershot and other large stations for instruction in ambulance and army hospital corps duty.

Promotion to the rank of Surgeon-Major to be after twelve years' service, three of which abroad ; but for distinguished service promotion to be irrespective of seniority. To the rank of Brigade Surgeon promotion to be by selection for ability and merit, provided the Surgeon-Major has had eight years' foreign service in all. From Brigade Surgeon to Deputy Surgeon-General, and from the latter rank to that of Surgeon-General. Promotion to be by selection. If appointed as Honorary Physician or Honorary Surgeon to Her Majesty, a medical officer, if under the rank of Deputy Surgeon-General, shall, if duly qualified, be promoted to that rank.

On completion of ten years' service a medical officer may retire on a gratuity or pension, if specially recommended by the Commander-in-Chief and Secretary of State for War. If retiring voluntarily before the age of 55, he is liable to be called upon to serve in the case of national emergency. A Brigade Surgeon, Surgeon-Major, or Surgeon, shall be placed on the retired list at 55 years of age. A Deputy Surgeon-General or Surgeon-General at 60. A step of honorary rank is attainable on retiring after twenty years' full pay service. Exchanges are permitted. Good service pensions are granted in larger numbers than heretofore. Sick leave may be allowed for six months, and in special cases for a second period of the same extent—that is, a year in all. Temporary half-pay is granted under particular circumstances to medical officers incapacitated for duty by illness.

Non-effective pay, or gratuity in lieu thereof, is granted. To a medical officer of 10 to 18 years' service a sum of £1,250 to £2,500 ; Surgeon-Major from 20 to 30 years' service, £1 to £1 5s. 0d ; Brigade Surgeon, £1 7s. 6d. to £1 10s. ; Deputy Surgeon-General, £1 15s. ; Surgeon-General, £2.

Retired medical officers, and medical officers of the Militia, are eligible for employment up to the age of 65, receiving during the time of such employment a consolidated salary in place of retired pay.

II.—THE INDIAN MEDICAL SERVICE.

By recent regulations the conditions of service, pensions, and honorary rewards in the Indian Medical Department have been in a great measure assimilated with those of the medical branch of the general army. It is right, however, that we allude to the fact that rumours are in circulation regarding further changes in the constitution of the Indian Department.

The examination usually takes place in February and August, when candidates are examined in the following *compulsory* subjects :—*a.* Anatomy and Physiology. *b.* Surgery. *c.* Medicine, including Therapeutics, the Diseases of Women and Children. *d.* Chemistry and Pharmacy, and a Practical Knowledge of Drugs. The examination in Medicine and Surgery is in part practical, and includes operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The *eligibility* of each candidate will be determined by the examinations in these compulsory subjects only.

Optional Subjects.—Candidates who desire it will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to Materia Medica ; and the number of marks gained will be added to the marks in the obligatory part of the examination, and position on the list of successful competitors will thus be improved in proportion.

Probation at Netley Hospital.—The competitor who obtains a place in the ordinary service is obliged to undergo probation of four months at Netley Hospital, where he attends the following lectures : Pathology, by Dr. Aitken ; Military Surgery, by Dr. Longmore ; and Clinical and Military Medicine, by Dr. Maclean ; Military Hygiene, Dr. de Chaumont. The lectures on Military Surgery include gun-shot and other wounds ; duties of army surgeons in the field, during sieges, on transport, &c., and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examinations of water, air, food, and clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professor of Medicine and Surgery, to make themseves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post-mortem examinations, to operate on the dead body, and to pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues,

&c. During his preliminary training here the student is understood to be in Her Majesty's Service; he wears uniform, is under military discipline, and receives pay as already stated. A sum of money, equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks, the fortunate young man who wins the "Blue Ribbon of Netley" being toleraby certain to be well provided for.

III.—NAVAL MEDICAL SERVICE.

The arrangements, time, and places for examination, the declaration to be made, and documents produced, the subjects and method of examination, and the subsequent probation at Netley, are to all intents exactly the same as those quoted above for the Army and Indian Medical Services:—

1. Every candidate must be not under 21 nor over 28 years of age. He must produce a birth certificate, or a declaration made from one of his parents; also a certificate of moral character, signed by a clergyman or magistrate, or by a Professor of the College at which he was educated. 2. He must be registered under the Medical Act as possessing two diplomas. 3. He must be free from organic disease, and will be required to make a declaration that he labours under no disease or weakness, or any other imperfection that can interfere with the most efficient discharge of the duties in any climate. His physical fitness will be determined by a Board, who are to certify that his vision comes up to standard, which will be ascertained by test-types. 4. Every candidate, immediately after passing this examination, will receive a Commission as a Surgeon in the Royal Navy, and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital.

IV.—ENGLISH POOR-LAW MEDICAL SERVICE.

The English Poor-law service differs in many respects from the Irish. Each parish in England and Wales has its guardians of the poor, and these parishes are grouped together to form unions. The unions are divided into districts for medical relief. A union medical officer therefore has the care of a district, and sometimes of a workhouse as well; sometimes only a workhouse. He is elected by the guardians of the union, and the appointment confirmed by the Local Government Board. He must have both a surgical and medical qualification, and be registered, and is required to name a duly-registered practitioner to whom application can be made in case of his absence from home; he can name his assistant or partner as his substitute. As a general rule, the guardians may not assign to any medical officer a district which exceeds in extent an area of 1,500 acres, or which contains a population exceeding 15,000 persons. This does not apply to Wales, but no such district may be assigned to a medical officer residing more than seven miles from any part of a parish included in such district. A medical officer is entitled to a fee of not less than 10s., or more than 20s. for attending a woman in or immediately after childbirth, and to a fee of £2 where great difficulty has occurred in delivery, or long subsequent attendance has been necessary. Many of the salaries of Poor-law appointments are very low—often so out of proportion to the work done that the medical officer must give his services for nothing, or next to nothing, as he has to provide all medicines, instruments, &c., except trusses, cod-liver oil, and quinine, for which he sends a statement to the guardians, who pay him the cost price; the paupers have to put up with those medicines which cost the least. In London and large towns some boards of guardians provide dispensaries, where the paupers are supplied with medicine, which relieves the medical officer from much labour and expense. It ought to be compulsory on all boards of guardians to provide dispensaries, and where this cannot be done, as in country districts, to provide all drugs, &c.

Clubs.—In England and Wales (more especially in the manufacturing districts) the medical practitioner derives much of his income from clubs, which pay him from 3s. to 4s. per head yearly, for which he visits and supplies medicines, &c.; the average payment for each visit amounts to the large sum of about 6d. Parish appointments are often sought for by young men as an introduction to practice, or by older men to prevent opponents setting up in the district.

V.—THE IRISH POOR-LAW MEDICAL SERVICE.

The newly-qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes in the great majority of instances upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 163 workhouse and about 808 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service averages about £103 15s.; and when it is taken into consideration that in the vast majority of rural districts it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a large margin left from the public emoluments. The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act passed in '73 and amended in '78.

The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality and is required to vaccinate every one who wishes to come. For each patient his fee of 2s. is paid, along with his salary, by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and, secondly, because, if not secured by the new comer they would of necessity bring a competitor for office into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save themselves the monopoly of their private emoluments.

Appointments.—The qualifications required by the Poor-law Commissioners are a Licence in surgery or a Diploma in medicine, and a Diploma in midwifery; the candidate must also be twenty-three years of age.

The appointment lies with Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter largely into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away.

Duties.—The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary to the termination of the same. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependent on the goodwill of the members of his committee. If the medical man be a favourite with his masters, they will give him very little trouble with "scarlet runners," as the visiting ticket are, from the colour of the paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye, even to the committeeman's own brother or daughter.

Workhouse Hospitals.—The number of unions in Ireland is 163, to each of which is attached a medical officer, who is appointed and controlled by the Board of Guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attandance at the workhouse hospital, and no night visits out of doors or any long journeys across the country are involved.

Superannuation.—A Poor-law medical officer *may* now receive a pension not exceeding two-thirds of his salary on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians ; nevertheless, it has been given in most cases in which physical incapacity has been clearly proved. There are now about 60 ex-medical officers receiving superannuation allowance, whose average term of service before pension was 20 years, and whose allowance averages about £60. Their average age at retirement was 63.

Complete information as to fees, emoluments, duties, and appointments of Irish Poor-law medical officers will be found in the "Irish Medical Directory" for 1883.

VI.—SCOTCH POOR-LAW MEDICAL SERVICE.

Practically these appointments, once made, are held *ad vitam aut culpam*, while in terms of the strict letter of the law they are but yearly appointments. Arbitrary dismissal is, however, guarded against by the powers of the Board of Supervision. It is expected that soon parochial medical appointments will be *legally* placed on the footing of permanent ones, and that a retiring allowance will be provided for the medical officers, as is the case in Ireland. The emoluments received from the local boards vary according to the number of paupers, size of the parish, and often the local exigencies requiring the residence of a medical man. salaries may be said to range, on an average, from £30 to £100 per annum. In remote and thinly-peopled districts the landed gentry and large farmers assess themselves in sums varying from £3 to £20 to make up an adequate income to the doctor, which, however, must be held in lieu of fees for medical attendance. Should such attendance, however, be much in excess of any such sum, the doctor is usually safe in trusting to the honour and generosity of the Highland gentleman, for this arrangement is more peculiar to the Highlands of Scotland. The young doctor has more speedy and easy access to "good society" in the country than in large cities; and perhaps better society than the latter : and should he be worthy of it he is certain to command respect and courteous treatment, and, with limited ambition and sporting tastes, to lead a useful and happy life.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

NOTICE.—The Editor desires to thank those gentlemen attached to the various Medical Schools for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO READERS.—As this number is devoted exclusively to information necessary for students intending to join one or other of the varions medical schools, and for those who, having passed their curriculum, are about to enter into the ranks of the profession, the ordinary matter which fills our columns is necessarily deferred till next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost.

ON

THE DIFFERENT FORMS OF APHASIA—ON WORD BLINDNESS. (*a*)

By J. M. CHARCOT, M.D.,

Professor to the Faculty of Medicine, Paris; Physician to the Salpétrière Hospital; Fellow of the Clinical Society of London, &c.

GENTLEMEN,—I purpose in several of the succeeding lectures to consider with you certain clinical aspects of aphasia. You will doubtless think that thereby we are apt to encounter difficulties of more than one form. The term aphasia, indeed, considered in its largest acceptation comprises, you will remember, all the various and sometimes subtle modifications presented by the faculty which man possesses of expressing his thoughts by means of signs (the signatory faculty of Kant). But that faculty or those faculties which enable us to communicate with our fellow creatures must be considered as associated with the highest functions of our nervous system, for if, properly speaking, they do not form an integral part of our intelligence itself, they certainly, as their derangements make manifest, exercise upon it the most decisive influence. You will therefore comprehend that a very delicate analysis alone, and a careful exposition step by step of the psychico-physiological phenomena which we encounter, will enable us intelligently to surmount the difficulties of our course. Accidents, indeed, have been favourable to us, for circumstances have determined in our wards the presence of several pathological cases of a simplicity and unequivocalness truly remarkable. These will permit us to study the fundamental forms of the aphasic syndrome, dissociated as much as possible from extraneous complications, and consequently in exceptionally favourable conditions for physiological analysis. A clinical exposition of one of these cases will form the subject of to-day's lecture; the reflections which arise from this investigation will be considered in a subsequent lecture. The case under consideration, if I mistake not, offers one of the best examples of a form of *aphasia* which has been recently described under a distinct title, by some authors under the name of verbal blindness (*cécité verbale*) (*wortdblindheit*, Kussmaul). I will not, at the present moment, attempt to define that which one understands by this term, that will sufficiently evolve from the description on which I am about to enter.

M. H. P., æt. 35, is a silk-mercer and hatter at T——. For the past four years he has been principal of the establishment; previous to this time he was the chief *employée* in a similar house. He is a man of average intelligence, his education having been early directed towards commerce. He entered the hospital on our recommendation, hoping thus to be more minutely examined and better treated, and he has remained several months under our observation. He is intelligent and active; he speaks and writes with tolerable accuracy. As he supervises his own shop he has occasion to speak much, and he writes as many as from twelve to fifteen letters per day. He frequently occupies his leisure in reading novels, and pamphlets. He reads very quickly, but has the habit of moving his lips in reading, and of pronouncing the words in a bass voice. He has been married for ten years, but has no family. If we examine into the question of *heredity* we do not encounter any nervous antecedent in his family history; his father is still alive, and his mother died of an affection of the heart or chest. His personal antecedents do not offer any special feature. He made the campaign in 1870 with the army of the East, when he suffered much. He has never had articular rheumatism, and no palpitation of the heart either before or after his accident. His pulse is regular (80), his heart is of normal volume, and there is no bruit. The sole affection which merits consideration is a headache, dating back to the age of fifteen, recurring two or three times per month. These headaches, which exist further since his accident, are sometimes so violent as to compel him to take to his bed for one or two hours. They present the following character: 1. The pain

---

(*a*) Translated from *Le Progrès Médical.*

before diffusing itself habitually occupies the right frontal region, a little above the eye-brow. 2. It does not appear to be accompanied with disturbance of vision. 3. There is no transient hemiopy (a) nor scintillating vertigo; there is no symptom of ophthalmic migraine, accompanied with creeping in the arms and hands, and no temporary *aphasia*. 4. These headaches are never followed by vomiting. These comprise the pathological antecedents. In short, there is nothing to observe which can be associated with the actual malady if we except the headache. This is a point which we will especially have to inquire into in the sequel. Let us pass, meanwhile, to the present history of the patient. On the 9th October last, being at a fox-hunt, he suddenly sees an animal half hidden in shrubs which he takes for a fox, at which he fires and promptly kills. Unfortunately, he killed not a fox but the dog of a friend to which he had been most attached. P— is deeply moved both on account of the dog and the vexation of his friend. Meantime, he continues the hunt, but disheartened and eating little. After lunch the hunt is resumed; a rabbit passes, P. aims at it, but at this moment he falls to the earth, we are assured, with paralysis of the right side; a few minutes afterwards he loses all consciousness. From the moment of this accident the recollections of our patient are very vague. He knows that he was carried to the railway to be taken to T——, which he recognised; but after that he again loses consciousness. He states that on reaching home he was immediately put to bed, and that he slept all night.

On the 10th October, when he awakened in the morning 1. He was completely paralysed in the superior and inferior extremities, which were absolutely flaccid and inert. 2. He stuttered in speaking, saying one word for another; his wife states that he said "one of my hands is asleep" (*paraphasie*). He recognised at that time forms and objects, but was unable to designate them by name; he could not even express the name of his wife. It is impossible to determine if at this period there was any deviation of his mouth or tongue, or any perversion of sensibility. About four days subsequently (14th October) he began to move his paralysed members to the extent of being able to raise them. He assures us that the superior extremity had become comparatively more free than the inferior. He dragged the foot for about a month subsequently.

On the 28th October an important manifestation occurred. He no longer experienced hardly any difficulty of speech, only from time to time he used one word for another. The hand is sufficiently under control to enable him to write freely. Wishing to give orders relating to his business, he takes a pen and writes; believing that he has forgotten something, he re-demands the letter to complete it, or rather to re-read it, and then there is manifested in its originality the phenomenon on which I wish specially to direct your attention: *he is able to write, but he finds it impossible to read his own writing.*

Thus we have a patient who had suddenly become *aphasic*, or rather *paraphasic*, with right hemiplegia; after some days the aphasia and hemiplegia disappear; the patient is able to write; he writes legibly enough to give an order; but, while he desires to read, is unable to do so. His writing at this period was almost what it was fifteen days later, that is to say, three weeks after the accident. Here is a letter, dated the 1st November, addressed to his mother, and it is interesting to compare it with another letter, dated the 22nd November, 1880, that is to say, three years previously. The first differs from the second only by a trifling peculiarity in the writing, the letters being more vertical and of a more infantine form, and by some errors of orthography which consist especially of forgetfulness of the "s" and "x" at the end of words and of one word, "with." We notice that in the letters written four, five, and six months afterwards these errors have disappeared and that the writing takes its pristine form. From the same period we notice it was impossible for him to read print; as difficult, and even more so, than a page of writing. Here intervenes an interesting accident in certain respects, but which I only note in passing because it does not appear to be directly related to the accidents which we specially desire to signalise. Fifteen days after the accident (towards the 24th October) he experienced a sharp lancinating pain in the right ear, continuing about two days, then a constant siffling, exaggerated when he is spoken to or when he is under the influence of a moral emotion.

But witness a fact more important perhaps, although it does not constitute one of the group of the perversions of language. Towards the 9th of November, that is to say, one month afrer the accident, he desired to play a game at billiards. He is right-handed, and his right hand perfectly free handles the cue with ease; but he suddenly experienced a loss as to where to play, for on the right side his field of vision was limited to the extent that he saw but the half of the green cloth of the table and the half of the ball, and that he lost sight of the balls when they entered into the right portion of the field of vision. This is the first mention which we have in the history of our patient of a right lateral hemiopy which has since been regularly studied by us for it exists at the present moment, though in less degree.

Resuming—when the patient came to consult us on the 3rd March, 1883, there existed no paralysis, no motor aphasia, he was able to write quickly and regularly, but he found it impossible to read print or writing; he had right hemiopy. But we must study more closely the condition of our patient at the moment that he presented himself to us for the first time. In the first place, he is a young man, with a lively eye, intelligent, steady gait, easy gesture, and presenting in no wise that embarrassed and dull air which aphasics so commonly present. Secondly, after his history had been recounted to us by himself under the control of his wife who was present, a task which he accomplished without difficulty and without our perceiving any slowness in the delivery, any substitution of words, and especially without any stammering, we were assured that notwithstanding his ability to write fairly, he was unable to read. We will enter upon this point in greater detail presently.

(*To be continued.*)

ON MEDICAL GALVANISM AND ANIMAL ELECTRICITY. (a)

By JOHN GRAY McKENDRICK, M.D., F.R.C.P., F.R.S.E.,

Professor of the Institutes of Medicine in the University of Glasgow; Fullerian Professor of Physiology in the Royal Institution of Great Britain.

In these days, when electricity is commanding universal attention as a great force capable of being made subservient to humanity, it may be appropriate to consider some of the phenomena of electricity produced by living tissues and by living organs—or what is called animal electricity. We must also remember that most of the modern developments of electrical science may trace their origin to the physiological experiments of Galvani, the Professor of Anatomy at Bologna, in 1786. Struck by the contractions of frogs' legs in the vicinity of a frictional electrical machine, he wished to study the effects of atmospheric electricity, and accordingly made his first experiment. Then he discovered that there might be a contraction of muscle on the connection of the nerve and muscle by a heterogeneous metallic arc. Then came the notion that the nerves conveyed electricity from the brain and cord to the muscles, and following the law that the new concepts of a man of science originate from ideas of familiar things, the muscle was forthwith compared to a Leyden jar, the inner surface of which became positive by nervous action, whilst the surface was negative. Motion was caused by the irritation of a kind of discharge, the positive internal surface being connected with the negative external surface. Volta doubted this, and held that the phenomena observed by Galvani were due to very feeble currents of artificial electricity produced by the application of heterogeneous metals to the limbs of animals. In the critical inquiry made by Volta into this question, he was led to the invention of the Voltaic pile, which not only for a time threw into neglect the question of animal electricity, but also was the starting point of the electrical science of the present day. In 1820 Oersted made the discovery of electro-magnetism. This led to the invention of the astatic needle (Ampère), and of the multiplier or galvanometer (Schweigger); and in 1827 Nobili constructed a galvanometer of great sensibility, by which he could reinvestigate the question of whether or not currents of electricity could be obtained from animal tissues. He found that such currents did exist, and he supposed they were due to thermo-electric action. About ten years thereafter (1837) Matteucci, of Pisa, again investigated the matter, and found that currents could be obtained from animal structures, even where all suspicion of thermo-electric or chemical action was removed. He also discovered that the interior of muscles was negative to their surface, and that it was possible to make a kind of battery from the thighs of newly-killed frogs, which could produce chemical effects similar to those caused by Voltaic elements. Then came the labours of Du Bois Reymond, the present Professor of Physiology in the University of Berlin, which will always mark the commencement of an epoch in the history of animal electricity. Recognising that the detection of the feeble currents from animal structures depended on the delicacy and accuracy of the apparatus employed, he made many improvements in the construction of galvanometers, and in the arrangements for leading off the currents from living textures into the galvanometer. Such galvanometers must be exquisitely sensitive, and it is evident that just in proportion as they are so, so will be the difficulty of making an arrangement which will lead off any current that may exist, say in living muscles, without causing a current itself. If we apply to a bit of muscle the ends of the copper wires coming from a delicate galvanometer we either get no effect or an effect due to the action of the muscle substance, or the fluid covering it, on the copper wire. We must have some arrangement which, while touching the muscle, will not cause any chemical change in it, and at the same time will draw off into the galvanometer circuit any current that may come from the muscle itself. That is, the electrodes of the galvanometer must be *non-polarisable*, even when touching muscle. Du Bois Reymond found that little troughs of zinc, filled with a saturated solution of sulphate of zinc, fulfilled these requirements. Into these are placed pieces of blotting paper, also wet with sulphate of zinc solution, and on the bits of blotting paper are placed morsels of clay moistened with saliva. When the bits of clay are put into contact so as to make a circuit, no current passes through the galvanometer, If we now take a muscle from the back of the leg of a frog, cut it across, and place it on the clay pads so that the section of the muscle touches one pad and the surface of the muscle the other, a current of electricity passes through the galvanometer, as shown by the swing of the needle. This was shown by the lecturer, a beam of lime-light being reflected on a screen by a mirror attached to the needles of a galvanometer. It was then shown that an uninjured frog's muscle gives no current; that no current can be got from two uninjured surfaces nor from two transverse sections; but only, speaking generally, when one clay pad touches a section and when the other touches a surface. This may be called the muscle-current. A similar current, though much weaker, can be obtained from living nerve. It was also shown that when a muscle is caused to contract, as it does naturally, the so called muscle-current is diminished; at all events, suppose the current from a muscle brings the needle of the galvanometer to a certain point, if the muscle then be caused to contract, the needle will swing back to nearly its zero point. The reverse—the so-called *negative variation*—indicates that an electrical change in the muscle happens when it contracts. But by refined methods of experiment it has been shown that this change really occurs *before* the muscle contracts, that is, the change in the electrical state of the muscle is an expression of the chemical changes occurring in it, which are antecedent to the muscular movement.

(a) NOTE BY TRANSLATOR.—Hemiopy (Eng.); ('ήμισυς, half, ὄπτομαι, I see); *halbsicht* (Ger.); an affection of the eye, in which the patient perceives only the half of the object looked at. It is due either to a partial paralysis of the retina or to a partial opacity of the crystalline lens whereby the rays of light are prevented impinging on the retina, or it may be due to some affection of the brain at the seat of origin of either of the optic nerves. Dr. Wollaston describes it as follows as occurring in his own person: "I suddenly found, after violent exercise two or three hours before, that I could see but half the face of a man whom I met; and it was the same with respect to every object I looked at. In attempting to read the name Johnson over a door, I saw only 'son,' the commencement of the name being wholly obliterated from my view.'

(a) Abstract of lecture delivered before the British Association for the Advancement of Science, at Southport, on Monday, September 24th, 1883.

The lecturer further showed how it was possible to measure the amount of those changes by Poggendorff's method of compensation, by which a fraction of the current of a Daniell's cell was passed through the galvanometer in the reverse direction to the muscle current. Thus, it may be determined that the electro-motive force of the natural current of a frog's muscle is about ⅛ of a Volt. Similar currents may be obtained from nerve, although they are very much weaker. Much discussion has taken place as to what these currents really mean; but the majority of physiologists agree with Hermann, of Zurich, in thinking that the current obtained on cutting or injuring the muscle or nerve is really due to the dying of the muscle or nerve substance at the point of section, and that the so-called "negative variation" is the current indicating functional activity. That is, living substance dies at the plane of section, and in dying it acquires a lower potential than the living matter, thus giving rise to a current. Again, suppose a living muscle giving no current, on stimulating it, by irritating its nerve, so as to cause the muscle to contract, a lower potential is produced at the points in the muscle where the nerve fibres end, and there is thus a negative variation. Further, it has been shown that this negative variation passes like a wave through the muscle substance, and that the wave has disappeared before the muscle contracts. If, then, electrical changes occur during the activity of muscle and nerve, it is natural that physiologists might expect to detect changes in the beating heart. This is the case. It was shown, by projecting its image on a screen, that the uninjured frog's heart, isolated from the body, still lives, and, whilst beating, gave with each beat an electrical variation, as shown by the swing of the galvanometer needle. The uninjured heart gives no current, but when slightly injured there is a variation in its electrical state with each beat. Then the lecturer showed that light causes an electrical change in the eye. Placing the eye of a frog in the galvanometer cushions, it was shown that there was a current passing from the cornea to the back of the eye. In the dark little or no change could be seen, except what might be due to the drying of the living structures forming the eye; on allowing light to fall on the eye, there was at once an increase in the current. This continued for a time, then began to fall, and, on light being removed, there was another increase, and then a sudden and rapid fall off. This action, first shown by Professor Holmgren, Professor Dewar, and the lecturer, showed a specific influence of light on the retina. It could not be called a negative variation. It indicated chemical changes occurring in the retina.

Lastly, the lecturer showed the production of currents from the living man. Placing the hands in two vulcanite troughs communicating by platinum plates with the galvanometer, and filled with a weak solution of salt, he showed that on contracting one arm a deflection of the galvanometer needle was produced. When both arms were quiet there was no current; on contracting one arm a current was at once produced. This current the lecturer was inclined to think was due to action of the fluid on the skin, and not to currents from the muscles, and that the differences were due to differences of contact.

In summing up, after a few remarks regarding electric fishes, the lecturer said that all of these electrical changes were really expressions of the vital changes occurring in living tissues under the action of stimuli. It was no part of the functions of nerves, muscles, or of the retina of the eye to produce currents under the action of their relative stimuli, but such currents indicated chemical changes in the organs or tissues; for example, the contraction of a muscle is a movement following or consequent upon many chemical changes, among the results of which were the production of heat and differences of electrical potential. Thus there was no special production of electricity, except in the case of electrical fishes, and possibly of some other animals. In most animals, including man, the production of currents was an incidental phenomenon, indicating chemical operations, and nothing more. Besides, the currents so produced were feeble and evanescent, and bore no relation to the general well-being. Consequently all attempts to influence the living body by magnets had no rational basis. The lecturer had tested this question by powerful electro-magnets, and had not been able to detect that they had the slightest influence on any vital phenomena. It need hardly be added that the so-called phenomena of animal magnetism are of an entirely different kind from those discussed. These are of a subjective character, dependent on peculiar states of the nervous system, having nothing whatever to do with electricity or magnetism, but still in a sense they are phenomena as real as those of physical science. Their subjective character, however, renders them specially difficult of investigation, and consequently they are more liable to fall into the hands of the charlatan. One safeguard against this is the recognition of what the electrical phenomena of the living body really mean, and one purpose of this lecture will be served if it shows that to detect and account for this phenomena requires the most refined methods of the physicist and of the physiologist, and that they give us only a glimpse into the intricate changes occurring in living tissue. The lecture was fully illustrated by experiments, in which galvanometers of the most sensitive construction were used.

◆

THE PHILOSOPHY OF VOICE.

By CHARLES LUNN.

(*Continued from page* 213.)

To strengthen the views and arguments of my past, I must now go into the deepest depths of the subject. It is not my intention of entering into the arena of metaphysical dispute, but on the other hand, it is important the reader know my standpoint. Let us take two authorities. St. Thomas Aquinas teaches that the body does not possess the soul, but that the body is possessed by it; that the soul is complete and entire all over the body, and in each part of it, and capable of manifesting itself in any given locality of its possessions by action. Professor Huxley holds that "All states of consciousness in us are immediately caused by molecular changes of the brain substance." And he goes on, that it seems to him "in men there is no proof that any state of consciousness is the cause of change in the motion of the matter of the organism." And then he draws his conclusion "Our mental conditions are simply the symbols in consciousness of the changes which take place automatically in the organism, and that, to take an extreme illustration, the feeling we call volition is not the cause of a voluntary act, but the symbol of that state of the brain which is the immediate cause of that act. We are conscious automata (*a*), endowed with free will." (*b*)

If we turn back to page 45 of the same work, we are told that science is "the knowledge of fact, of which every verbal description is an incomplete and *symbolic* expression," Professor Huxley adding, "Be assured that no teaching of science is worth anything as a mental discipline which is not based upon direct perception of the facts, and practical exercise of the observing and logical faculties of them." Professor Huxley and I are one in holding the practical man of fact better than the theoretical man of imagination—a doctrine I commend to the numerous hypothetical writers on voice production—and I venture to hold, with Dr. Huxley, that a "symbol" is "incomplete," or of less value than the thing it symbolises; so that I cannot believe with him an act of volition is but a "symbol" of material change, *i.e.*, an "incomplete" thing in mind of a complete thing in matter. What I *will* is the vital point to me, not what molecular changes may or may not be going on in the laboratory unknown to me.

It should be noted that on the material side Mr. G. H. Lewes, who alleges the spinal cord is a seat of volition, has never been disproved (see his "Physical Basis of Mind"). Let me put the relationship of mind to body thus: As the extrinsic principle of the unity of a body is the union and communion, co-ordination and subordination, of its head and members; so the intrinsic principle of its unity is the abiding presence within it of our spiritual life-giving soul.

The metaphysical crux how far our material structure can be regarded as objective phenomena for consciousness to interrogate may, then, be left; it is only my business to interrogate one part of its mechanism. Given consciousness—which I hold as one aspect of that life that sustains the body—we have, in this general term, the three particulars: The memory, the understanding, and the will. I am not going to discuss whether "volition" is a symbol, but I take it that actions are symbols of it. Let us see what Will is not. It is not projected as a thrown stone; it is not transmitted as a wriggle down a rope; it is not even circuitous, but it is located. It goes to its *end* not round about, as bent nerves go; it is as though a telegraph clerk entirely neglected his own material end, and commenced to act at the other end, where he is not. The will is a weight which, acting upon a balanced scale, makes one side kick the beam. And now I will bring this on to the question of voice production. A similar outer manifestation in body may be produced by un-similar means; a flush may come from shame or from physical work; the aspirate H may be made by will, or may result, in multiplied iteration, from running, "panting" being a number of aspirates mechanically produced by reflex action. Let us follow out this neglected physico-philological aspect. In the open aspirate H the will looks in the same direction as the expiring air, and accelerates its flow; the letter F is only H resisted by the lips, the letter S is H resisted by the tongue, and V is F with voice added to it, as Z is S with voice added to it—two locks in a flowing canal. What the lips are to voice in the letter V, and what the tongue is to voice in the letter Z, so the false cords are to the true cords in true voice production—namely, by ruling

---

(*a*) I do not like the word "automaton" introduced into physiology. It seems a confusion of terms. An automaton is a thing that appears to have life, but has it not. Is a "conscious automaton" a thing having life, but appearing not to have it?

(*b*) Science and Culture, "Animal Mechanism," p. 239.

the escaping air in restricted flow, they supply a physical balance on which the metaphysical balance depends. The habit of allowing the false cords to be neglected and fall apart, is acquired physically by consonants, and mentally by mislocation of will. To give an illustration: Some of my readers will remember an entertainment called "The Organophonic Band;" the performers imitated various instruments by means of voice and mouth. I had the advantage of a personal examination of one. What the compressed air in the blown out cheeks when sounding the buzzed sustained consonant B was to their vocal tone, associated with lip resistance, so the compressed air in the blown out ventricles is to the invisible but artistic voice. In brief, the set *Ah* of the old school is suppressed escape at false cords with voice added to it, and this physical equilibrium—the hydrostatics of voice—has its mental equivalent, a perfect physically unfelt control. The training to attain this consists in making the will look, as it were, the other way, and meet the breath at the organ of voice.

But, before further argument I have to trace the false thought that has grown up side by side with the true.

Madame Seiler's school of sight was incalculably strengthened by the approval of Professor Helmholtz. It was to counteract this influence that I exposed his fallacy respecting the physical basis of hearing by pointing out that birds, having no "fibres of Corti," hear better than we do, and that therefore Nature has either made two ways of conveying the same thing to consciousness, or birds do not hear musical sounds, or the "fibres of Corti" are not the means by which men apprehend them. Great men trip outside their sphere. (*a*)

Now one result of this patronised misuse of the laryngoscope has been to create a class of professed teachers who are neither trained singers nor members of the medical profession, until the world cries out to us as follows:—

"A lady recently said to us—'What shall I do to cultivate my daughter's voice? I am anxious to do something to develop and beautify her voice, yet every teacher of singing and elocution I happen to know has a voice much harsher and rougher and more discordant and disagreeable than hers, and I'm afraid to have her even associate with them, and still more to have her take lessons, for their methods must be false.' Truth compels us to add that some of the sweetest, pleasantest voices we have ever heard were those of persons who had never taken a lesson in elocution or in singing, while some of the most grating, crackling voices we have met with were those of professional voice teachers! What's the matter?"—"The Voice," American paper, March, 1883.

To come nearer home. Mr. Lennox Browne, whose "Medical Hints" followed so soon my papers in the *Medical Press and Circular*, writing of the misuse of the laryngoscope, says:—"Valuable as has been the laryngoscope in a physiological, as it is undoubtedly in a medical sense, it has been the means of making all theories of production of voice too dependent on the vocal cords." Had Mr. Browne stayed here, his work would have done good, but, venturing beyond it, did harm; it distracted attention from the chief condition of voice restoration, the location of will, and restoration of parts, where, of the two points of resistance, the weakness is apparent, and centred attention on modes of breathing. Metaphysically, he misdirected the will; physically, he neglected enfeebled parts. But more. He weakened the old law of "Complete Inflation," as he did not seem to know that all good singers sing, even at softest, with compressed air through the complementary, through ordinary breath, down to the last particle of supplementary air that can be used. This state of statical and hydrodynamical balance is known to a singer by a perceptible grip between larynx and chest muscles, felt as the grip between finger and thumb is felt. Bad singers sing without compression, and the grip looses itself. This I ventured to term, using a strictly physiological word, "The Tonicity of Voice." But we have a greater than he in error. I would respectfully entreat Professor Huxley to reconsider his statement that the depression of the thyroid heightens pitch, and that the elevation of the thyroid lowers it ("Elementary Physiology," p. 183). It is incalculable the mischief this has done in training, and the disproof is easy. Sing a scale upwards, and the thyroid is felt to rise. The explanation is this: One cartilage ascends quicker than the other, both ascending; and the effect on cords attached is the same as though one cartilage were fixed, while the other descended.

The "fixed larynx" theory and "low larynx" theory are the outcome of this slip.

But one of the worst books that has been published is Herr Behnke's "Mechanism of the Human Voice." If argument were needed to induce educated men to take the question up, this work would suffice. Let me give two examples, and their disproof by a known authority:—
